I generally leave my HP48 in the lab... so that leaves me using Google Calculator all the time ;-) I'd forgotten that the HP48 is good with complex numbers so I should probably start carrying it home...

Google Calc is useful in that it knows units, and it knows many the fundemental physical constants... so you can do all sorts of cheating.

Throw this into the Google search box:

1/(2*Pi*4MHz*50 picofarads)

or try:

0.625*(c/14.030MHz) in feet

73,
Dan

Instead of dragging your calculator home all the time, why
not go to hpcalc.org and download an emulator program for
your PC?

From: richardharrison@webtv.net
Message-ID: <22658-451F1DC2-627@storefull-3251.bay.webtv.net>
Source record: 51833

Alan, VK2ADB wrote:
"What sort of feed warrangement did you use?"

600-ohm open-wire line. Many of the rhombics I erected were made from U.S. Army WW-2 Signal Corps kits. These used three cables in the diamond shaped curtain which came together at the end supports but were spread apart by several feet at the side supports. This construction tended to further reduce impedance variations as frequency changed. We didn`t bother with this refinement with receiving antennas.

Actual antwenna driving point impedance tended to exceed 600 ohms so width of the attachment point to the anteena was wide for the cable size to appear as about 800 ohms and then the spacing tapered steadiy down during the descent to the horizontal transmission line which was spaced for 600 ohms.

The cable used in the kits was made from (3) AWG 12 Copperweld wires twisted together. There was also stainless steel wire for a dissipation line at the far-end of the rhombic. We had to replace this with larger wire as we were broadcasting with 100 KW transmitters, far more power than anticipated by the Signal Corps. Under some conditions and at some frequencies, it is possible to dissipate up to 50% of the power fed into the rhombic in its dissipation line.

It is possible to operate without a dissipation line or resistance. The rhombic becomes bidirectional without the termination. I know from experience during a period when the Signal Corps dissipation lines melted from the broadcast power and our fan mail came from South America as well as Central Europe.

Best regards, Richard Harrison, KB5WZI

Both are 90 degree elbows- from my measurements the ones that have a square block of metal at the elbow were fine. The ones that looked like a 90 degree plumbing sweep had bad return loss. This may vary from mfg to mfg, but Al Ward W5LUA who has had experience up through 24GHz agrees.
Perhaps I'll get time and inclination to mill one of the sweep styles open and see what's up.
Dale W4OP

Are YOU qualified? We gather more information about our environment
from vision than any other sense. Now, that's NOT to say that we have

the best vision in the animal kingdom. Our vision is refined and
depended on at the expense of our other senses. Ever have a pet cat or
dog that was blind and deaf? I have and you would be surprised how
well then can adapt with just the sense of smell and touch alone.
Humans need some degree of assistance.

>And pixels show emotion?

This is an strawman. You know full well what I mean.

I'll tell my daughter's occupational therapist to quit using a monitor
screen to teach her how to recognize emotions of people's faces
pictured on the screen. After all, I have just been told that you
can't view a persons mood by the look on his face if it is composed of
pixels on a screen.

>When you actually get into high school, let us know.

That was uncalled for and childish. Your arguments are based on a
false premise that I and other want to ban the use of CW or that it is
useless. We're only opposed to it being required to pass a test. I
question those who say it's as good as a human voice. It isn't and you
can't say otherwise. Romanticize it all you want. It is what it is.
Nothing more.

We gather more information from fellow humans by words than by any
other means. And words aren't processed in the visual cortex, not
even written words.

>Ever have a pet cat or
>dog that was blind and deaf? I have and you would be surprised how
>well then can adapt with just the sense of smell and touch alone.
>Humans need some degree of assistance.

Apples and oranges. Deaf-blind people get along pretty well too, if
they're given food, water and all the comforts of home by someone
else.

>Why would I want to leave usenet?

You don't like CW because you can't tell emotions on CW. Since you
can't tell emotions on Usenet, you evidently don't like Usenet. Or
you're being inconsistent.

>>> I don't speak Ukrainian but I sure knew when my grandmother

>This is an strawman. You know full well what I mean.

Since I can fully communicate using "emotionless beeps", no.

>I'll tell my daughter's occupational therapist to quit using a monitor
>screen to teach her how to recognize emotions of people's faces
>pictured on the screen. After all, I have just been told that you
>can't view a persons mood by the look on his face if it is composed of
>pixels on a screen.

No you haven't, but you're being told that if you're not being

>>When you actually get into high school, let us know.

>That was uncalled for and childish.

It was completely called for.

>Your arguments are based on a
>false premise that I and other want to ban the use of CW or that it is
>useless.

The original discussion was about requiring it, not banning it. My
attention span's not that short.

> We're only opposed to it being required to pass a test.

So be opposed to testing altogether. Oh, there's already a way to get
on the air without a test. You just don't like that way. Now that's

being childish.

>I question those who say it's as good as a human voice.

How can you question a language you don't even begin to understand?

>It isn't and you can't say otherwise.

Sure I can - I understand and use it - you don't, so you can't
intelligently discuss what it is or isn't at all.

More like model has a problem capturing or reflecting reality.
Modeling will calculate the pattern etc., but will not properly reflect the interaction of the antenna design with propagation medium and terrain/surroundings, like showing effect of capture area.

Antenna modeling tools aren't intended to model propagation effects. But
the stronger the signal radiated in the right direction, the stronger
the received signal will be. And the strength of the radiated signal in
each direction is what the antenna modeling program shows.

As for the "effect of capture area", the "capture area" of an antenna is
just another way of stating the gain. This information is what you get
from an antenna modeling program.

My turn to say apples and oranges then. Can you quote where I said
that I didn't like CW? Basically, I say that it's only good for
submitting raw data, like usenet. Didn't say that it was a bad thing,
just not a full, complete way to engage in human discourse. It should
also not be a barrier to the use of amateur radio.

>
>That's what this discussion is about, so I guess the grandmother story
>is just a red herring.

No that was NOT my point. Let me be more precise: The inflection added
by actual voice results in a conversation that is much more than the
sum of it's parts, the parts being the words used. My grandmother
example simply showed that inflection adds so much more to a
conversation that it can, at times, convey some information on it's
own without words.

>> Usent is text, by the way, not visual.
>
>I'll have to start using my ears to read your posts, then.

Raw data [text] is all that's needed for this conversation.

>>>>>Your insularity is showing.

>
>The discussion was about communication. YOUR discussion. You started
>it. Did you forget what you were talking about?

You insist on reducing the term "communication" to just an exchange of
data. I am trying to point out that there is MUCH more to human
interactions than just data.

24. Optimising a G5RV

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-01 04:43:50 UTC
From: Owen Duffy <owen@no.where>
Message-ID: <jtguh2lh8mqdlm5lsg0aus2qtgk6tdbkug@4ax.com>
Source record: 51848

Some months ago I put some thoughts together to assist our newly minted 6-hour hams who seem attracted to either short end-fed wires (although they refer to them as long-wires) or G5RVs.

This article deals with optimising a typical G5RV (as distinct from an optimal G5RV).

I ceased efforts when it became apparent that the procedure was beyond the base competency level for our Foundation Licence, and therefore beyond the target audience. (Another issue was that it required transmitting a test carrier on 20m which is not one of their permitted bands, so technically they would need assistance.)

Nevertheless, I looked over it today and fixed a few typos.

http://www.vk1od.net/G5RV/optimising.htm

Comments welcome.

Owen

>The numbers are down for a variety of reasons, but I suspect that
>computers and the internet are the major factors, not the CW
>requirement.

The ready-built Personal Computer first appeared in 1976,
30 years ago (the "IBM PC" debuted in 1980, 26 years ago).
The Internet went public in 1991, 15 years ago.
"Restructuring" to drop the morse test rate to 5 WPM
for all such tests happened only 6 years ago.

The peak licensing of 737,938 happened on 2 Jul 03, just
3 years ago. [they've been dropping at an average of 7K
per year ever since]

I disagree on your reasons stated in your quote above.

>When I ask technical people about why they haven't
>acquired an interest in amateur radio, I never get the CW requirement
>as a response.

Strange, I hear that response. Having been IN radio-
electronics for over a half century, I DO know some
"technical people." :-)

Manual radiotelegraphy was a MUST to use early radio
as a communications medium. The technology of early
radio was primitive, simple, and not yet developed.
On-off keying was the ONLY practical way to make it
possible to communicate. Morse code was then already
mature and a new branch of communications was open
to use by downsized landline telegraphers.

> They simply view the whole service as outmoded in the
>face of modern telecommunications.

PART of that IS true. NOT all of it.

What IS outmoded (technically) is sitting only on HF
and "working" other stations with morse radiotelegraphy.
Amateur radio is the ONLY radio service still using

morse radiotelegraphy for communications purposes.

Another thing outmoded is the strict "necessity" to use a formalism in "procedure" AS IF it was "professional" radio. That formalism was established between 50 to 70 years ago. Amateur radio, by definition, is NOT professional. Too many olde-tymers want to PRETEND they are pros in front of their ham rigs.

But, there is still an enormous area of the EM spectrum that is still open for experimentation, for just the fun of doing something out of the ordinary above 30 MHz. That can be a very different RF environment, much much different than the technology available in the 20s and 30s. It has exciting possibilities...except for the rutted and mired olde-tymers unable to keep up with new things, secure in their own dreams of youth and simple technological environment.

>Let's face it.. the romance is gone.

Oh, boo hoo...the "romance" of the 1930s is gone? Yes, it IS. The "pioneering of the airwaves" below 30 MHz has been DONE...mostly by the pros of radio (despite what the ARRL claims). DONE a long time ago. The solid-state era came into being about 45 years ago and has revolutionized ALL electronics (radio is a subset of that).

Except as memorabilia trinkets of the past, GONE is the analog VFO, GONE is the one-tube regenerative receiver, GONE is the single-crystal-single-frequency Tx, GONE is the big, bulky AM modulator amplifier, GONE is the not-knowing-when-the-bands-are-open (solar activity and ionosonding solved that and HF MUF is a predictable item that can be found by a computer program). Except for the boatanchor afficionados, vacuum tubes are GONE for nearly everything but high-power transmitters.

The radio world of today is NOT that of 1950, nor of 1960, nor 1970, nor even 1980s. It keeps changing, advancing, the state of the art never static. For the stuck-in-the-mud olde tymers that is terrible...they feel insecure on not being able to keep up, become aggressive to newcomers ("no kids, lids or space cadets") and retreat to the "secure" mode of their youth, "CW." But, they want to make sure They get the respect they feel they've "earned" (as if) so they try and try and try to bring all down to THEIR level...the code test MUST stay..."because."

There are 100 million two-way radios in use in the USA alone, millions more in other countries. Those are the

cellular telephones. There are millions of VHF and UHF transceivers in the USA, working daily for public safety agencies, ships, private boats, air carriers as well as private airplanes. There are tens of thousands of HF transceivers in use in the USA, users being everyone from government agencies to private boat owners, ALL exclusive of amateur radio users. Where is the "romance" in all this Plenty from a cornucopia that all have grabbed? It is GONE, yes.

But, NEW "romances" await. DIFFERENT ones, I'd say a helluva lot more complex than old, simple "radio." We can't relive old "romances" except in our minds and we can't grow physically younger. Only person-to-person romance is TRUE, the other "romance" is of the imagination, of the fantasy of what was once there. This fantasy "romance" can't be brought back. It can't be legislated into remaining static. The rules and regulations have to change to keep up with the NOW.

If you really are an amateur operator, why can't you give out
your license callsign?

How DOES one have a "reasoned debate" with an anony-mousie
such as "Nada Tapu"?

I've not seen that such is possible in here except for two and
both of them are self-admitted Canadians.

LenAnderson@ieee.org

"Magic" is a subjective term. The "magic" of HF worldwide comms
dissolved into reality for me in 1953 on seeing such wholesale
"magic" working 24/7 in tying US Army (and other military) into
the large network going back to the states.

"Different strokes for different folks."

ARRL is still fixated on HF and the "magic" of morse. Since they
influence (if not brainwash) as many US hams as they can with
their huge publishing effort, we aren't supposed to negatively

critique them. That's "not nice" to those who've had their brains washed in that way.

I've seen "real" magic at the Magic Castle in Hollywood, CA. That's mainly a professional association of magicians/illusionists. One can't gain entrance without being admitted by a member. I've had the marvelous opportunity to go in three times there...and be totally fascinated by the illusions. Whenever I see some ham bring up "magic" I think of the Magic Castle. A lot of hams ascribe "magic" to HF comms but that is their own private illusion (or delusion, as the case may be). Shrug. To each his own but I don't like others trying to cram Their delusions into everyone.

I can help a little, just not at 450 MHz.

In the 1970's I had the TV system on an aircraft carrier for maintenance. One slow day at sea, I tested the connector-loss stories. I took the longest piece of RG-59 I had (about 60' or so) and measured the loss around 60 MHz, Channel 3, the freq of my test generator. Next, I joined about ten pieces of RG-59 together to make the same length and repeated the measurement. I was surprised at my result: only about 1 dB more loss. Certainly nothing like the mythical 1 dB per connector figure that had been bandied about. Plus, crimped-on F-59 connectors have nothing to recommend them, compared to N-type connectors we use for UHF hamming. I did not have any right-angle F-connectors to test then. I have some now and I have modulators I can tune to UHF to source a stable signal. Maybe I'll run some more tests.

Not a bad idea. There's a diagram or three in Laport's "Radio Antenna Engineering" so I'll have a bit of a read.

I like the tapered arrangement. What's the minimum distance needed to
taper from 800 to 600 at freqs from say 3.5MHz to 14MHz? I did one years
ago from 130 to 200 and it was about a foot long at 1.8GHz.

Alan,

Are you tapering for impedance transformation, or just to reduce
transmission line losses?

I make the matched line loss on a 600 ohms open wire line with 2mm dia
copper spaced 150mm something approaching 0.1dB/100m, with 2:1 VSWR
you are talking ~0.14dB/100m. You should find the rhombic no worse
than 2:1 unless it is too short.

My loss calculator has an ideal air spaced 600 ohm copper line (copper
loss only) 2mm/150mm, the label is "Open / air dielectric (150/2.00)",
you can try the various loads from the NEC models for more exact loss
figures.

Probably because it's not safe to go waving around more information than you
have to.

http://www.blogs.oregonlive.com/oregonian/newsupdates/default.asp?item=194639
Dispute On CB Airwaves Leads To Fatal Shooting

Yes, the non-CB amateur bands tend to be a little more mature than the
citizens band (or at least as far as the
Washington/Clark/Multnomah/Clackamas County area is concerned).
Unfortunately, Usenet and the Internet are not. If you don't believe me,
go watch Dateline when they sting Internet weirdos sometime to see the
worst of them.

This is a very strange result, the non 90 degree elbow ones, normally
referred to as "swept radius" are intended to reduce the step
discontinuities that the a 90 elbow type introduce. They are usually used at
microwave frequencies where these discontinuities are more apparent.

Great job as usual, Owen. I would add a couple of
items.

1. Some commercial antennas, sold as G5RV's, deviate
from your information because they deviate from your
specifications and tuning procedures. They may need
to be tuned to your specifications.

2. The following statement is somewhat confusing.

> Fig 1 shows the efficiency of a optimised typical G5RV.
> Note that only three of these peaks coincide with an amateur
> band, but 40m efficiency is 65% although not at the peak.

The resolution of the graph makes it difficult to know which
three peaks are in which three bands. Like 40m, you might also
state that 15m efficiency is xx% although not at the peak.

<<that would be a very interesting experiment I guess i could hack saw
open a regular 90 elbow rt angle but i thinkk i know what i would find
and guess why they wouldn't work well could be wrong i have no test
gear.... but i couldn't open the 'square' one it's not easy to hacksaw
the one i have has a 'screw' at the square elbow but its cosmetic it
won't 'openup'

i really should find someone w/some sort of test rig and take some
N-->pl259 and etc adapters as well as some 90 adapters and do a
experiment if i win the lotto i'd buy a rack of test gear (only a
ham nerd would do that)

thanks very much

> PA3DJS

sounds like you are having fun, goodluck at the jamboree what type of
antenna did you design?

I live in nyc, and couldn't travel that far to take a class actually
my crazy dream was to have the class here around nyc and more
'practical' ham related going over different antenna topics (for ex)
from the simple/to advanced 'stuff' theory/design/actual etc

maybe a few other related topic's heck i cant even find any good
videos or classes to cover upgrading to Extra, i have the arrl book,
it's more of a test guide than a step by step too bad there wasn't
a instructor led upgrade to extra class around i'd pay up

i think i knew of a few places that used to give begginers training but
not sure if those same ones' are still around

my local ham store had test gear i used to be able to 'play with' but
they closed up long ago

i may be wrong statistically speaking but i think it's odd that the
states w/the highest ham population by far have the least ham radio
stores

ps my ex girlfriend was from freezland

thanks for all
ml

These are serious questions I have of CW operation, with no harm, malice, hurt, or put-downs intended for anyone, so I hope this thread does not degrade to that point.

When listening to CW on my scanner, are there any tell-tale indications that the operator is dyslexic? Does a dyslexic ham use the same speed, protocol and " short-hand/short-form wording " as a more proficient ham would use in communicating CW? Do dyslexic hams ever really use CW, or would dyslexic hams ever even consider the use of CW on a regular basis? Are dyslexic would-be hams able to pass the CW portion of an exam to get into a higher class of license and increased privileges?

I meant these as very real and serious questions. I have a dyslexic daughter which I'm still trying to comprehend and understand by trying to view reality as she sees it. Wifey and I are somewhat still feeling guilty of having eroded her self-esteem when we were raising her by using usual methods of discipline when she screwed-up excessively, until we finally realized that there was a very real problem that needed dealing with, but in non-usual ways. This is 25 years later, and I still feel like shit about the situation and go way out of my usual way to help her without making the other 3 siblings feel left out, so maybe we should lighten up on some of the dyslexic guys/gals in these newsgroups for having the balls to be here in the first place, let alone wanting to communicate with those who do not have a dyslexia problem.

More power to the dyslexics...I think they should be made to feel welcome. The crappy name-calling should stop, though.

Jack

some are able to dylexia comes in degrees not all dyslexics are afected
to same degree

OTOH I know of No dyslexic ham that has been able to USE CW onnthe air
without being roundly flamed by the other users of CW

...Nope..." high " was the last word, and I left out a " dot " on the last "
h " to make it an " s " as in " higs " instead of " high " . Just testing
to see if anyone out there cared enough about CW at all to catch
that...Proved my point, I guess :) :) :)

But whenever a far-field NEC model uses any kind of real ground in the analysis, modeling the effects of the propagation environment along with the native radiation launched by the antenna is exactly what occurs.

This is why some think that the far field radiated by a vertical monopole less than 5/8-wave high is zero in the horizontal plane, when in fact at every operating frequency, it is always the highest field the antenna produces.

True enough. But...the coders HAVE their rank-status-
privileges and seem to enjoy looking down on no-coders.
All must do as they did or be called "wrong" or "in error."

Early radio was just a telegraph system without poles and
wires between stations. Mythical tales have turned early radio
into something greater than rocket science.

"Ore" from a mine. The pro-coders say "I've got mine, nya-nya."

It's getting to be "Back to the Future, Part Infinity" if things like the Great 500 KHz Experiment is a sign of things to come from the "representative of all amateurs" in Newington.

Their other "Experiment" is a "contest" to see who can best come up with a whole ham station for LESS than $50 in new part costs. Whoever "wins" that gets a really hefty prize of $100 cash and Publication in QST! Oh, and it is 40 meters only, but "allows" SSB voice to be included. :-)

Hello,

Did you have a Dutch Girlfriend? Friesland is one of the northern provinces of the Netherlands (The Frisian capital is Leeuwarden). I live some kilometers north of Utrecht (in the middle of the Netherlands).

Regarding the antenna for the JOTA. It is a simple center fed halve wave double wire dipole (to increase useful bandwidth a bit) with parallel ground wires (1.5m above ground) to reduce the losses in the soil just below the antenna. The height above ground level will be about 11m. According to simulation, the overall radiation efficiency (ground losses included) will be about 80%, so we are not going to heat the worms that much.

It has maximum radiation in a vertical direction. It will be used for local (300km) traffic on 80 meters (Near Vertical Incidence Sky wave). Just 2 days ago we received permission to use a sufficiently large open area (with some domestic sheep) adjacent to the scout's building.

I had some ideas for other antennas (for 40m and 2m), but without permission for using the adjacent land I don't want to spend time and money.

The reason for an antenna optimized for local traffic is that most scouts are a little bit nervous, they are not used to SSB quality sound and their English is not that good for international contacts.

Best Regards,

---------- REPLY FOLLOWS ----------

A vertical as you describe is a good transmitting antenna but is somewhat more susceptible to picking up local man made noise than is a horizontal dipole. Local noise such as from motors, arcing, etc, starts out with all polarizations but the horizontal component is quickly attenuated by travel over the earth's surface. The vertical component is not, and therefore is received by a vertically polarized antenna. Because vertically polarized signals are not attenuated when using groundwave mode, AM broadcast stations use it exclusively, or very nearly so. They also use enough power to overcome the noise pickup issue.

If you live in a relatively quiet environment, you may not notice the difference, and the vertical will have a very low angle of radiation, good for DX, and will probably outperform the horizontal in that respect.

The best of both worlds is to have both antennas available and be able to switch between them as needed. Highly recommended.

Bill, W6WRT

Hi Owen--great job! But you said "comments welcome", so please don't be offended by what I have to say.

I have always been curious about all the hype, excitement, and marketing popularity of the G5RV, So I included a section on this antenna in both editions of Reflections, ed 1 in 1990, and ed 2 in 2001, in an attempt to educate the newcomers to its realities. So I invite you to read the pertinent section from the book below:

The following is a quote from Chapter 20 in "Reflections-Transmission Lines and Antennas," authored by W2DU.

"Sec 20.2.4 The G5RV Antenna

With this background on random-length dipoles behind us, it seems appropriate to make a critical examination of a particular 102-foot dipole that is enjoying a great deal of popularity--Louis Varney's G5RV dipole. In spite of its popularity, its operation is not well understood among many amateurs, so I'll shed a little light on the G5RV. First of all, the reason for the 102-foot length for the G5RV is no secret, but it is not well known. Being unaware of certain antenna principles, many amateurs have come to believe that there is some sort of magic in the 102-foot length, and that their all-band success with this antenna is dependent on this specific length. Nothing could be further from the truth, because, except for 20 meters (as I'll soon explain), any random length of at least 3 lambda/2 long at the lowest operating frequency will perform equally well.
What is the significance of the 102-foot length? Unbeknown to many amateurs who use it, Varney designed the antenna to be a resonant 3 lambda/2 radiator on 20 meters--that length is 102 feet. He had two specific reasons for selecting 3 lambda/2 on 20--he wanted a four-lobe radiation pattern and a low feed-point impedance. The 3 lambda/2 was a clever choice, because this length yields a

four-lobe pattern, in addition to a low feed-point impedance that can be matched to a 50-ohm line with a line transformer without requiring an antenna tuner. As Varney also intended, this 102-foot length results in a strictly random length on all bands except 20, so except for the 20-meter considerations I've just described, there is no magic whatever to this length. The last comment in the previous paragraph should be taken seriously. It should be noted that the 102-foot length of the G5RV is almost exactly the length I recommended above for a random-length antenna, 3 lambda/8 at the lowest frequency of operation, because 100 feet is the length required for 3 lambda/8 at 3.5 MHz.
On 20 meters, the input impedance of the 3 lambda/2 G5RV radiator is low because the feed point is at the center of the central 1/2 wl portion. Hence, the impedance (the resonant resistance) is only moderately higher than if the outer 1/2 wl sections were eliminated, leaving a single 1/2 wl dipole. At the frequency of mid-band resonance, the free-space feed-point impedance is approximately 100 + j0 ohms, which reduces to around 90 + j0 ohms at a convenient height above ground. This results in a mismatch of about 1.8:1 relative to 50 ohms. Varney's choice of the 34-foot line-transformer matching section, 1/2 wl on 20 meters, was to make a 1:1 impedance- transformer that repeats the 90 + j0 antenna impedance at its input terminals. Thus, with a suitable choke balun to make a transition from a balanced to an unbalanced line, the low 1.8:1 mismatch makes connecting to a 50-ohm line feasible without requiring an antenna tuner. The SWR on a 1/2 wl matching section of 300-ohm line is around 3.3:1, while on a 450-ohm line it is about 5:1. Keep in mind that these considerations apply only to 20-meter operation. On all other bands, the G5RV antenna terminal impedance is much higher and reactive, resulting in a higher SWR and making the use of an antenna tuner imperative. Incidentally, the length of a 3 lambda/2 radiator may be found using the long-wire antenna formula
length in feet = 492(n - 0.05)/f MHz, (Eq 20-3)

where n = the number of half wavelengths in the radiator

It is unfortunate that many amateurs believe that the balun should be omitted. These people have been misled, because failure to include a balun between the balanced open wire and the unbalanced coax results in RF radiation in the shack from current flow on the outer surface of the coax shield.
In addition to the misunderstanding concerning the "magical" 102-foot length of the G5RV, there are also other areas of confusion focused on this antenna, some concerning the role of the feed line. There are some who believe that a particular combination of open-wire and coaxial feed line yields a perfect 1:1 match on all bands without a tuner. As stated above, this is true only on 20 meters. Others believe that because the 102-foot dipole length is shorter than 1/2 wl on 80 meters, a certain length of the feed line is a folded-up portion of the antenna to make up for the difference in length, and that the folded-up portion radiates along with the antenna. Still others believe certain lengths of feed line are to be avoided to prevent "antenna current" from flowing on the feed line because of line resonance. Patently untrue! I wish I knew how these myths originate.
My own involvement with the G5RV antenna dates back to the early '70s when I began lecturing on SWR and reflections on transmission lines. My lectures promoted the use of antenna tuners with open-wire feed line on random-length antennas as the best way to achieve all-band operation. I also promoted the

concept that the correct length of feed line is that which is required to reach from the antenna terminals to the tuner, because, regardless of the length of the feed line, both the feed line and the antenna are made resonant by the conjugate matching action of the tuner. Hence, there is no reason to avoid certain lengths to prevent line resonance, because the tuner makes them resonant anyway.

I first heard of the G5RV when someone in my audience described his 102-foot antenna with open-wire and coax feed line. He claimed it gave him a 1:1 SWR on all bands without a tuner. I told him he must have a lossy coax to get 1:1, because I knew a 1:1 would be impossible with such an arrangement without some exceptionally high resistive loss somewhere in the antenna system. After hearing several more identical claims in later lecture sessions, I analyzed the antenna on all bands, observing it to be the 3 lambda/2 that it is on 20 meters, but a random length on all other bands, so I felt confident in rebutting the ridiculous "1:1 on all bands without a tuner" claims. Incidentally, Varney published an update of the G5RV in The ARRL Antenna Compendium, Volume 1 (Ref 112), in which he presented the same specifications for the antenna that I described above, which confirms my earlier observation that his antenna is 3 lambda/2 on 20 meters, and a random length on all other bands.

Let's now examine the other myths and confusion concerning the G5RV that I mentioned earlier. First, we'll consider the feed-line combination believed to yield a 1:1 match on all bands. It has been written that the combination of 33 feet of open-wire line, plus 68 feet of 50-ohm coaxial line will yield such a match. Don't you believe it! A determination of the G5RV antenna-terminal impedance on all bands shows that there is no length of open-wire line of any characteristic impedance Zo that will transform the antenna impedance Za to an impedance that is even close to presenting a match to 50- or 75-ohm coax, except on 20 meters. However, when fairly long lengths of coax follow a length of open wire, the high SWR appearing at the junction of the open wire and the coax will be reduced significantly at the input of the coax because of the attenuation loss in the coax, especially at the higher frequencies. The longer the coax, the lower the input SWR, but remember that this method of lowering the SWR is costly in terms of lost power. Because an antenna tuner is necessary anyway, except on 20 meters, it makes no sense to use any coax at all. Coax performs no useful function in the feed system, and it consumes power unnecessarily because of the high SWR. A more sensible method is to run the open-wire line all the way to the tuner and eliminate the coax entirely.

Second, let's consider the length of feed line believed to be a folded-up portion of the antenna that radiates. Radiation occurs when the electromagnetic field developed by current flow on a conductor is not canceled by an opposing field developed by an equal current flowing in the opposite direction. Hence, radiation occurs as a result of current flowing on an antenna. However, antenna current ceases being antenna current at the antenna terminals, because once it enters the transmission line, the current becomes transmission-line current, with the current in the two conductors flowing in opposite directions. There is no radiation from any portion of the line, because the fields developed by the currents flowing in opposite directions in the two conductors oppose and cancel each other throughout the entire length of the line. Therefore, no portion of the feed line becomes part of the antenna."

Owen, I didn't include this to detract from your excellent work--you've done a great job. But my position is that since an antenna tuner is necessary anyway for the antenna to be multibanded, why insert any coax at all?

Walt, W2DU

wrote:

>This is why some think that the far field radiated by a vertical monopole
>less than 5/8-wave high is zero in the horizontal plane, when in fact at
>every operating frequency, it is always the highest field the antenna
>produces.

Given the anachronism of mixing the explicit far field with the
implication of an unexpressed near field in the statement above, it is
reasonable that some might "think" something. The bare statement is
rather given to pondering, wondering, and ultimately puzzling:

What is the comparison being made?

A vertical monopole to a 5/8-wave high antenna? A vertical monopole
that IS a 5/8-wave high antenna? The far field to the near field? For
either a vertical monopole OR a 5/8-wave high antenna? For the same
vertical 5/8-wave high monopole antenna?

To what purpose?

Are we being steered toward the argument that the far field
representation of radiation would force someone to renounce their
experience of a strong signal received, at ground level, and within
sight of the antenna? This may appear to offer the temptation of a
paradox, but such opportunity is so rare as to be wholly outside of
the commonplace MF/HF activity of Hams.

After-all, even considering AM frequencies (160M) and that 5/8-wave
tall structure, there is no such thing as a zero angle signal beyond
26 miles. This range would be a stretch even then, as it demands an
angle depressed BELOW zero degrees from the aeronautical beacon at the
very top of the antenna. The zero angle range must then be something
radically less. And being less, it would be of no interest to the
average Ham. Thus the paradox of confabulating two different
radiation characteristics is lost.

As often happens, ray-tracing demands an origin, and yet an antenna
radiates from the WHOLE of its surface, not the aeronautical beacon,
nor its base insulator. To obtain that zero angle radiation
characteristic demands that the entire antenna (or certainly a
majority portion of it) be in sight. Let's simply mandate the average
height of a 5/8ths-wave for the 160M band being a 50M high point
origin for this ray-tracing exercise. The zero angle would fly over
the head of every radio in the audience who lived below that height.
In fact, most ordinary Hams would be hard pressed to erect an antenna

that high in the first place. Again, common experience would dictate a healthy signal, but it would not be a treasured DX contact, and it would probably be considered obnoxious QRM.

Even though such a signal (seeing only half the height of the antenna) comes from being 18 miles away (on a billiard ball smooth planet), it demonstrates the NEAR FIELD properties of optical ray-tracing and what would be called a zone of confusion. 18 miles away is well outside of the RF near field, but the argument of radiation lobes's characteristics is an optical geometry and 18 miles is sufficiently close enough to confound the two meanings arrived at in the quote above.

Hi Walt, I agree with what you said and here is an addition.
A graphic on my web page shows why the G5RV is decently
matched by coax on 75m and 40m as well as 20m.

http://www.qsl.net/w5dxp/G5RV.HTM

The 1/2WL of 300 ohm series section is what the antenna
needs to repeat the resonant feedpoint impedance on 20m.
I still don't know why Mr. Varney installed the 1/2WL
300 ohm section for 20m operation. Why not 100% coax?

The 1/4WL of 300 ohm series section is close to what
the antenna needs to transform the 40m feedpoint impedance
to a nearly pure low resistive value. This can be seen
on the Smith Chart.

The 1/8WL of 300 ohm series section is close to what
the antenna needs to transform the 75m feedpoint impedance
to a nearly pure low resistive value. This can also be
seen on the Smith Chart.

The 0.88WL of 300 ohm series section is close to what
the antenna needs to transform the 12m feedpoint impedance
to a purely low resistive value. I didn't bother showing
this one because it goes more than once around the Smith
Chart.

The purposes of my post were to state that (1) many NEC evaluations show a combination of the radiation from the antenna PLUS the propagation effects for the chosen earth parameters and antenna elevation, and (2) even when such an approach shows zero field in the horizontal plane for a ground mounted vertical monopole up to 5/8-wave high, that h-plane field in reality is NOT zero _as it is radiated_ by the antenna.

In fact for distances just into the far-field region for the radiator defined in (2) above (far field usually being defined as further than 2H^2/lambda from the antenna), h-plane relative field is virtually 100%, regardless of ground conditions.

This is simply an example of misusing a tool, not the evidence that it
lacks the capacity to show characteristics as they exist. Anyone can
conspire to fail.

As I pointed out once before, NEC (EZNEC in particular) will exhibit
fields from any antenna that are consistent with Brown, Lewis, and
Epstein's field data to within 1dB. I would further note that their
data all exhibited values that lay below 100% (if by 100% that is
meant to be theoretical).

AFAIK, neither NEC 2 nor NEC 4 from any source will show a composite elevation pattern over a defined ground at a specified distance to include the space wave and the surface wave in a single display. One must merge them using his/her own understanding and resources.

RF

84. beam SWR change going from low to high above ground

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-01 21:51:34 UTC
From: Ralph Mowery <rmowery28146@earthlink.net>
Message-ID: <GLWTg.3905$Y24.2457@newsread4.news.pas.earthlink.net>
Source record: 51908

I will soon be going up with a Hy-Gain TH3. This 3 element beam is now 17 feet above the ground on the side of the tower. Just put it there to check the SWR. The beam has directions for either low,mid or the high end of the band. I have is set for the mid position. As of now the SWR curve for all three bands are lower than the lowest frequency swr chart shows. Can I expect the SWR curve to go higher in frequency as I go from 17 feet to the final height of about 58 feet ?

I am using a current balun (beads on the coax type) the Wire Man sells if this makes any differance.

This seems to ramble well off the earlier path encapsulated by Denny
and apparently subscribed to by Owen, in regard:
>>But to bring us back to the major complaint which seems to be that the
>>Nec engine doesn't model the last few degrees over ground very well, so
>>that the zero angle is discarded by the software... Richard seems on a
>>mission to prove the NEC engine wrong - well, I agree, the NEC engine
>>does have limitations for low angle signals which is why the authors
>>have installed an angle cut off... Per Richard's citations
To which I object to, to no notice (I wasn't surprised however).

This subsequent restriction to GRAPHICS (and not to issues of NEC per
se) merely highlights my earlier comments that such "merging" serves
no apparent purpose of the Ham's activities in MF/HF, especially when
such GRAPHICS would only support a region of one to a dozen or so
miles. There is nothing remarkable or noteworthy in this indulgence.

To bring us back to the major complaint.... That complaint is without
foundation. EZNEC easily models the last few degrees over ground very
well (and to all constraints offered). Having said this, I, for one
(out of at least three) can see a contradiction. I, for one (out of
at least three) can support my contentions with data taken directly
from EZNEC whereas all other discussion to this point has been
particularly void of informed content.

So, I return to those same, earlier queries:
>>> What is the comparison being made?
>>>
>>> To what purpose?

Hi Ralph,

Such questions always deserve answers by degree. Yes, sort of. Let's
say you stand to observe less difference from 17 to 58 feet than from
3 feet to 17 feet.

Try the short cut of tuning the antenna pointing straight up (at
whatever short height).

Your BalUn is probably OK.

I am not sure if "3 lambda/2 long at the lowest operating frequency"
is what you really meant... perhaps I am misunderstanding it.

Copying a quote from one of my articles, "my experience is that where
a centre fed dipole less than about 0.35 wavelengths in length, it is
difficult to achieve acceptable feed system efficiency in practical
configurations". In fractional terms, I would state that minimum

length as about 3/8 wavelength.

> What is the significance of the 102-foot length? Unbeknown to many amateurs

...

I heard this story from an amateur friend (now deceased) who knew
Louis in the old country, and he used chuckle at the newfound role of
the G5RV as an efficient all band antenna (which it isn't).

...

>It is unfortunate that many amateurs believe that the balun should be omitted.
>These people have been misled, because failure to include a balun between the
>balanced open wire and the unbalanced coax results in RF radiation in the shack
>from current flow on the outer surface of the coax shield.

Agreed. Unfortunately Varney confused the issue with his later article
that rescinded his advice to use a balun.

I think the words in may latest article "Varney originally described
the G5RV with a balun at the coax to parallel line transition, and
changed his mind in a later article due to uncertainty about the balun
design. More has been learnt of baluns and antennas in the meantime,
and there is no doubt that inclusion of an effective choke balun at
that transition will assist in minimising feedline contribution to
radiation, and conversely, feedline pickup." are valid.

>Owen, I didn't include this to detract from your excellent work--you've done a
>great job. But my position is that since an antenna tuner is necessary anyway
>for the antenna to be multibanded, why insert any coax at all?

Agreed Walt, and no offence taken. Discussion of the issues is what
our hobby is (or was) about.

Our dear departed friend Reg would hop into me when I wrote about
G5RVs suggesting that I sold the things, that my perspective was that
of a salesman and that I was not detached. He was wrong, I have
erected a G5RV for the purpose of experiencing the thing, of learning
about it, but the trade-offs involved in a G5RV haven't suited my
interests for more than that few hours.

The graphs in my two G5RV articles are based on thousands of model
outcomes, starting from NEC models of the radiator in a typical
configuration, and then exact transmission line models and tuner
models.

The thing that I have learned is that most of the loss in typical
configurations is in the coax, the loss in the coax is driven by what
it happening on the radiator and open line section, and that reduction
of coax loss is the key to efficiency. An obvious way to reduce coax
loss is to reduce (even eliminate) the coax (though a systems
perspective shows that you don't just deduct the coax loss, ATU loss
will increase marginally at some frequencies). That is the subtlety in

my words "This article deals with optimising a typical G5RV (as distinct from an optimal G5RV)" The theme being that if you have a typical G5RV, here is how to go about getting the best out of what you have, if you want to improve it, read the other article linked at the bottom the page.

It is not a marvellous bit of prose, is it. I added the bit about 40
as a balance that although there wasn't a peak in 40m, 40m was well up
the curve. I will rethink a clearer way of expressing it.

>
>The resolution of the graph makes it difficult to know which

>state that 15m efficiency is xx% although not at the peak.

Yeah, I didn't really want to deal with how good a "typical" G5RV was
or wasn't rather just set the stage for why it was worth fine tuning
in situ. I stated in my posting our newly minted hams like them, and
when you start with a power limit that is 10dB behind the average, you
don't need to throw more power away in the antenna system.

But you're being inconsistent. You only want to eliminate code
testing because YOU can't see any merit in code. Many people can't
see any merit in knowing the laws or in having any technical

knowledge, so why not eliminate testing altogether?

Because you want your views to determine what's done. No other cogent reason.

>Others who want to end code testing generally feel the same way. This >is well established.

Yes, it is. They want everything done the way they want it - just like you.

You want to get on the air code-free, use the no code bands - CB. You want to get on frequencies that allow code? Pass a code test. It's not rocket science.

>>>I question those who say it's as good as a human voice.

>>How can you question a language you don't even begin to understand?

>I have already pointed out that you can get much information beyond >just data. And, no matter what you say, beeps are just data.

To you. Why should that matter to the FCC? As I said, you're not qualified to discuss something you have absolutely no understanding of - let alone make decisions about it for others.

>Keep on using it then. But don't tell me that I must know it in order >to use my voice on the radio.

You can use your voice on voice bands - called CB. That's what CB is for - communications for those who don't want to pass a ham test (which includes CW). Like you.

Neither NEC-2 nor NEC-4 shows a display of any kind. Output is solely in the form of tables of numbers. Surface wave data, when produced, is always combined with the sky wave as a total field value. It's chosen with an option on the RP input "card". The NEC-2 manual as well as NEC-2 itself -- including source code which enables you to see exactly how the calculations are done -- are freely available on the Internet. So there's no need to speculate about what it does or doesn't do.

EZNEC demo, standard, and plus program types don't include the surface wave in far field outputs, which as I explained in an earlier posting in another thread(*), isn't of much practical use to most amateurs. However, when needed the data can be obtained from the near field analysis (which is actually a total field analysis and isn't restricted to the near field). EZNEC pro program types (EZNEC-M and EZNEC/4) allow direct inclusion of the surface wave in the far field analysis, mostly for the use of AM broadcast consultant customers. It provides tabular and graphical outputs in the form of an azimuth plot at any desired horizontal distance from the antenna and height above ground. Like NEC, the output is the total field, or in other words the sum of surface and sky wave, and the results should be virtually identical to those from NEC.

(*) I recommend that anyone interested in this topic read the posting I made just a few days ago, Sept. 28, on this newsgroup under the thread "Elevation Patterns of Ground Mounted Vertical Monopoles". It can easily be located at http://groups.google.com if it's not still on your newsreader client.

It's funny, and most telling. The no-code hams have everything over 30
MHz, but it's the code hams that are the one's moving ham radio forward
and doing anything technical wise. I guess the no-coders are still trying
to figure things out.

Try to stick to one argument at a time. You were arguing for voice -
now you're arguing against it. Or is just any argument that might
possibly be construed to make CW look bad?

>>>Ever have a pet cat or
>>>dog that was blind and deaf? I have and you would be surprised how
>>>well then can adapt with just the sense of smell and touch alone.

Deaf-blind dogs and cats don't normally walk around the streets
without aid. (Domesticated cats, btw, aren't scent-oriented, they're
vision-oriented.)

>>>Why would I want to leave usenet?

>>You don't like CW because you can't tell emotions on CW. Since you

And you don't want to use it - but you do want to use Usenet.
Inconsistent.

> Didn't say that it was a bad thing,
>just not a full, complete way to engage in human discourse.

Neither is voice.

> It should also not be a barrier to the use of amateur radio.

It's not a barrier to USING radio - it's a barrier to one particular
hobby, which incorporates CW as part of itself. You want to ride a
bike as a hobby but not use wheels?

Code - ham.
No code - CB.

If that's too complicated for you to grasp, maybe you should take up
grass-watching as a hobby.

>>>>> I don't speak Ukrainian but I sure knew when my grandmother

>own without words.

So if she screamed at you, in Ukrainian, with her face all screwed up,
"You were so good!", you'd get the proper information, that she was
about to take you to the wood shed for the terrible thing you'd done.
Right?

I can convey as much emotion in CW as your grandmother could in
Ukrainian. You don't understand CW, so you can't understand how that
could be true - which is why you're not qualified to discuss the
matter.

My job is like describing the difference between red-orange and orange-red to someone who's been blind from birth. "Red-orange is redder than orange-red." "But ..." No buts - it is. Someone who's never seen just can't understand.

>>> Usent is text, by the way, not visual.

>>I'll have to start using my ears to read your posts, then.

>Raw data [text] is all that's needed for this conversation.

Raw data is all that's available for communication.

>You insist on reducing the term "communication" to just an exchange of
>data. I am trying to point out that there is MUCH more to human
>interactions than just data.

There's much more to human interaction than lexical communications, yes - but we're talking about lexical communications here, so anything else is totally irrelevant. You can't have any more than lexical communication by radio.

But tell bees that their dancing is just raw data. Then translate a bee dance for me, blind man.

Maybe the point was that a lot of us who can read CW should wear their
glasses when reading it on a screen. I swear I saw it as an H. Even
the second time, after I read this post. (That's what astigmatism
will do to you.)

> . . .

I'm not aware of any such problem with NEC, or any "angle cut off"
intentionally included in NEC(*). As Richard says, EZNEC has no problem
extending analysis of any kind -- near field, far field, or (in pro
programs) far field with surface wave, down to ground level. The value
of zero for far field sky wave (that is, far field at distances beyond
which the surface wave has decayed to essentially zero) at zero
elevation angle for horizontally polarized waves over any ground and for
vertically polarized waves over non-perfect ground is a rigorously
correct result. It follows directly from calculation of ground
reflection coefficients, the simple formulas for which you can find in
Kraus' _Antennas_ and many other references.

I'd be very interested if such a limit exists, and would be very
grateful to anyone who could point to the place in the NEC code where it
occurs, or provide an example of a model producing a result where its
effect is evident. I strongly suspect that whatever effect is being
seen, it's due to misinterpretation or other causes and mistakenly
attributed to a limit which doesn't exist.

(*) There are many places in the NEC and EZNEC code where protection is
provided against divide-by-zero errors, which limits internal
calculations and perhaps a minimum or maximum field strength or angle.
However, these usually limit a minimum divisor value to something on the
order of 10^-10 to 10^-20 or so, beyond the point at which a calculated
result is significant or, often, even valid.

This is as may be, and can be useful when properly understood and applied.

But is it not true that for the ground-mounted monopoles defined in my previous posts, no form of NEC and its Windows shells will show in a _single_ evaluation whether in tabular or graphical form, the net values of the surfacewave+spacewave elevation pattern at a user-specified distance over real earth, for all elevation angles in a given azimuth slice?

There is a typo in the above sentence. "3 lambda/2" should be changed to read "3 lambda/8". Sorry about that, my ploof reader goofed.

The point of the matter (re-iterated by Roy) is that the graphical
representation is one for wide application (99.9999%) and the
remaining (0.0001%) still have access to the DATA. There is nothing
lost but convenience. True, one may come to some erroneous conclusion
on abstracting the near-in characteristics to the far field
representations. I would challenge them more for their
mis-application than their literal mis-understanding, however. There
is not much demand for 160M operation to the horizon that goes wanting
elaborate modeling. Simple experience eclipses that easily.

To cut to the nut of the matter:
>>>But to bring us back to the major complaint which seems to be that the
>>>Nec engine doesn't model the last few degrees over ground very well
is simply wrong in the first degree (also re-iterated by Roy).

I've been modeling for results at the horizon for as long as I've held
a copy of EL/EZNEC. This and the Brown, Lewis, Epstein data confirm
to within 1dB as I've reported on more than one occasion. This is a
validation in the absolute, not relative sense; and to a probable
higher degree of accuracy than the average Ham pursues or could
obtain.

NEC can do that in a single run. You'll need an RP "card" for each point on the curve, each specifying the horizontal distance and zenith angle of the observation point. The reason that so many "cards" are necessary is that to maintain a fixed distance from the antenna, the horizontal distance must decrease as the elevation angle increases. And specification of distance in NEC (and EZNEC pro) is done as horizontal distance, not radial distance. See the NEC-2 manual for detailed information.

In the more than ten years EZNEC pro has had ground wave analysis, I believe your recent request is the only one I've ever gotten for such a display. Apparently EZNEC pro users, like me, don't see any practical use for one.

I'm surprised that Roy didn't take credit for this where credit is
due.

The near-field table (which complete conforms to your constraints) can
be expressed in a spherical coordinate system. I've used this feature
often.

There is this pithy little thing I found in the ARRL Handbook:

The Amateur's Code

The Radio Amateur is

CONSIDERATE...never knowingly operates in such a way as to lessen
the pleasure of others.

LOYAL.........offers loyalty, encouragement and support to other amateurs,
local clubs, and the American Radio Relay League, through
which Amateur Radio in the United States is represented
nationally and internationally.

PROGRESSIVE...with knowledge abreast of science, a well-built and
efficient station and operation above reproach.

FRIENDLY......slow and patient operating when requested; friendly advice
and counsel to the beginner; kindly assistance, cooperation
and consideration for the interests of others.
These are the hallmarks of the amateur spirit.

BALANCED......radio is an avocation, never interfering with duties owed
to family, job, school or community.

PATRIOTIC.....station and skill always ready for service to country and community.

--The original Amateur's Code was written by Paul M. Segal, W9EEA, in 1928.

Kind of old, and flavored a lot like the US was during the time, but
never-the-less, it has some important lessons in behavior and compassion
that seem to be lacking in your vision for the hobby.

-Chuck Harris

This was NOT weather. This was seismic. The runway was rising in spurts sometimes as much as 3 feet in an hour. And, in that era all the comms were microwave and had been knocked out by the big quake. 80m was all he had.

> In 1964 (which is 42 years ago), the weather stations had their

> think it important since I know it was NOT via amateur bands.

At that time Alaska was tied into the networks by microwave. When the quake shifted towers, we lost it all.

> NOTAMs take many shapes but back 40+ years ago, the
> FAA handled them and saw to their distribution at airports.
> Most were press-printed but some current ones were sent
> by TTY. That was in times before NOAA.

Yes, I know. I was working at Kimberly Aeradio in BC at the time of the quake. It was violent enough to leave a small mark on my barograph, even at that distance. The guys in Edmonton lost all circuits to Alaska and in short order we knew that we had a HUGE communications emergency on our hands (not to mention a real disaster).

At least I was in a position to put the information on the proper teletype circuits addressed to the proper authorities.

I don't remember now. Those were interesting days. And that kind of
emergency, while it can still happen, would be mitigated today by the
fact of satellite telephones, GPS and so forth that don't depend on local
power or microwave comms. Indeed, cell phones would probably have held
up in most areas if the towers were halfway decently designed and
powered....

It was all the microwave dishes on towers that moved a tad that made it a
real communications emergency. If I were to have to deal with one like
that today, I'd probably vote for using some digital mode, such as PSK31
or Olivia to move the traffic. But all we had back then was 850 shift
RTTY and not very much of that. It was another two years before I got

mine going (170 shift by then already!).

Contrary to Blow Code's fantasies, "the reports of my demise have
been exaggerated." [more or less a quote of Samuel Clemens]

I've never had a heart attack, have never died. Now quit imaginging
things that haven't happened. If you keep on, the new moderating
team may make you sit in the corner.

I only ever had the use of one REAL rhombic. And that was on 60m in the high arctic (gov't freqs). It was properly designed for the specific path we were using and yes, it was VERY good. You could almost make your own band opening with 5kw!

Properly designed, they have a good reputation for doing what the theory says they will do. Just remember, though, that you're going to have to sewer almost half your transmitted power into the terminating resistor. But that's the half that would be going the wrong way, basically.

>>The fact that I fully support technical testing is well established.
>
>But you're being inconsistent. You only want to eliminate code
>testing because YOU can't see any merit in code.

No, there are thousands and thousands of us who want to
eliminate the US amateur radio code test for any
license. It isn't confined to Jim-"Opus".

Go read ALL the comments to last year's NPRM from the
FCC. I did. Can you?

If you look real close you will see that the FCC doesn't
think that the code test is necessary for their needs
in determining which amateur applicant should get a
license. It didn't in 1990, it didn't in 1998, it
didn't in 2004.

The rewrite of Radio Regulation S25 at WRC-03 eliminated
the international need for all administrations to test for
radiotelegraphy for privileges below 30 MHz. It is
optional to include or exclude by all administrations.
The International Amateur Radio Union wanted that rewrite.
The ARRL did NOT. The IARU won.

> Many people can't
>see any merit in knowing the laws or in having any technical
>knowledge, so why not eliminate testing altogether?

Illogical, incosistent reasoning. The discussion is about
the radiotelegraphy test, a stand-alone test solely for
manual radiotelegraphy. It is NOT about the written test
elements so why mention them? [rhetorical question]

You MUST mention the writtens as somehow "related" but
it never was. It's a common ploy by pro-coders but
still irrelevant.

>Because you want your views to determine what's done. No other cogent
>reason.

Tsk, tsk, tsk. Insulting insinuation there. Bad form.

>>Others who want to end code testing generally feel the same way. This
>>is well established.
>
>Yes, it is. They want everything done the way they want it - just
>like you.

Tsk, tsk, tsk, more insulting insinuation of alleged
"bad conduct." :-)

>You want to get on the air code-free, use the no code bands - CB.

There is only one "CB band." It requires NO TEST at
all. Never has. :-)

>You want to get on frequencies that allow code?

I've been on many, many "frequencies" that didn't require
radiotelegraphy, either in use or to obtain a license to
operate. Got one of those licenses in 1956.

>Pass a code test. It's not rocket science.

It's unnecessary and certainly NOT a "science." :-)

The only agency in the USA that grants amateur radio
licenses is the FCC and they don't think the code test
proves anything to them insofar as granting any amateur
radio license.

>Why should that matter to the FCC?

Ahem, the FCC is the ONLY agency that grants amateur radio
licenses in the USA.

>As I said, you're not
>qualified to discuss something you have absolutely no understanding of
>- let alone make decisions about it for others.

Klein, you are now violating the general to-be rules of
moderation.

Jim-"Opus" is a Canadian. He is licensed under the jurisdiction
of Industry Canada, NOT the FCC. That is his ONLY "qualification
for exemption" in any discussions about what the FCC does or may
do.

YOU, on the other hand, NOT being IN the FCC, cannot legally
"make decisions about (the code test) it for others." That
decision is up the FCC.

What YOU seem to want to do is force everyone current and
future to take that code test...because you had to take a
code test...and you want to "get even." :-)

>You can use your voice on voice bands - called CB.

Incorrect. There is the Maritime Radio Service. There is the Aeronautical Radio Service. There is the Private Land Mobile Radio Service. There is the little Citizens Band Radio Service. All have bands below 30 MHz and all allow voice. [I've been on all of them] It isn't restricted to just CB.

>That's what CB is
>for - communications for those who don't want to pass a ham test
>(which includes CW). Like you.

Now, now, lets not get testy there old timer. Citizens Band Radio Service was established in the USA in 1958, 46 years ago...as a general-purpose, short-range communications band that would suit the general citizenry. It required NO test whatsoever back then, still doesn't require any test. CB has changed, enlarged in the following 46 years and the number of users outnumber all licensed USA radio amateurs by at least 4:1. [with no licensing for decades, only gross numbers of unsers are possible through sales records such as EIA reports]

I believe that Canada has their own CB. Many countries do. That is irrelevant to the retention or elimination to the radiotelegraphy test for USA radio amateurs.

Now be nice and behave in here or the moderator team to be might make you sit in the corner.

Shalom,

LenAnderson@ieee.org

I think there is a significant proportion of the Ham population that
refers to just about *any* wire antenna as a G5RV. I've heard about half
wave G5RV's, Coax fed, ladder line fed, (as in doublet) lots of
variations! ;^)

Perhaps getting the best out of it is to lower it to about 4 feet, and use it as a cattle fence? As noted above, we might as well eliminate the coax altogether.

123. DRESSLER ARA-HDX-100 $350 shipped

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-02 00:43:10 UTC
From: safetypro <bfdp1@msn.com>
Message-ID: <1159749790.731071.257960@m73g2000cwd.googlegroups.com>
Source record: 51797

Really need to sell this guys so here is the "deal" Universal sells
them for $550

My PRICE IS $350 shipped..................

ARA HDX 100 Active Receiving Antenna

40 kHz -100 MHz High Dynamic Range Model for urban locations. For
Base and Mobile, Land and Maritime (Useable through the FM broadcast
band)
Applications:

VLF and HF Shortwave listening
Scanners, Monitoring
Commercial Communications

ARA HDX 100 Technical Specifications:

Type: Omni-directional whip
Polarization: Vertical (may be mounted horizontally)
Whip material: Fiberglass
Frequency: 40 kHz - 100 MHz
Gain: 7.5 - 9.5 dB
3rd order IP3: +55 dBm
Noise Figure 4 - 6 dB
DC Power Supply: 12.5V @ 200 ma (included)
The HDX models are designed to withstand a higher level of ambient
signal level and are best suite for urban locations with high ambient
RF levels or any other site in close proximity to high power broadcast
or other communication transmission services.

Coax/Connectors: 40' RG - 58U, Type N(F)/BNC (M) with PL-259 adapter
The coax is connectorized at antenna base The ARA antennas are small,
light and very easy to install. Even indoors, they provide excellent
performance across their entire band ranges without any tuning. The ARA

HDX-100 compares favorably with long wire antennas in terms of signal
strength. In addition, the ARA products are "Electrically Short" and
offer the advantage of receiving a lower level of disturbances due to
electrostatic discharge and other man made (QRM) noise. The ARA low
profile also offers wind resistance to 100 MPH, when mounted on a
suitable structure.
All standard ARA models provide about 7-15 dB of gain (depending on
the model) and low noise figures which can enhance the sensitivity of
most shortwave receivers. LMR-240 (Ultra-Flex) low loss cable is now
included as "standard" with all ARA UHF products. The low loss
cable typically increases signal sensitivity by about 6 dB* as compared

to using standard RG-58/U cable.

Nonsense. ALL cats (especially domesticated ones) have POOR
vision. They are scent-oriented.

If you've had cats at all you would realize this.

Now why are you gabbling about biological subjects in an amateur
radio policy newsgroup?

>> But tell bees that their dancing is just raw data. Then translate a
>> bee dance for me, blind man.

Now why are you gabbling about biological subjects in an amateur
radio policy newsgroup?

Did you get stung while exiting a cat house?

Be nice Klein or the moderator team to be may make you sit in
the corner.

125. Attic Antennas and Foil Backed Barriers

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-02 00:44:55 UTC
From: "fgraves525@gmail.com" <fgraves525@gmail.com>
Message-ID: <1159749895.068600.14750@k70g2000cwa.googlegroups.com>
Source record: 51799

Hello,

I searched this group first and didn't find an exact answer to my situation. I have a large attic in a single story 2100 sq ft. house. I just bought this house a few years ago and it is to be my retirement home. Recently, I got the ham radio bug again and have most of my new gear here ready to go and I overlooked the fact that there is foil on the back of my attic roofing. I am disabled and cannot get in the attic easily and usually have to get my wife or somelse go up there. So I overlooked this.

I want to operate most VHF but I like 20 CW and 10 FM and 6 meters - 440 mhz both SSB and FM. So I've been trying to come up with an antenna to cover that. I have the antennas pretty much decided but Bingo -- the roofing material problem pops up and I don't have any idea how much signal I will lose through that stuff. If it is a few DB and messes the pattern up a little I don't care, but if it is 20 db and won't tune I do care. I'm not a contester -- just like to have fun and have a 100 Watt FT-857D and I'll keep the power down to were I don't start triping the GPFs :)

I have used a HT downstairs and never suspected a problem because it was a little VX-2R and I mostly just listened with it but I could hear all the repeaters and the aircraft band came in like gang busters and SW Broadcast was loud on a little whip. I just sold the HT when I ordered the new rig so I can't make the tests I would like up in the attic now.

Does anyone have any experience with this kind of attic. I have heard everything from it wont work to people that said it worked better than in other standard plywood attics.

I thought a shield had to be at "ground" potential to effectively block a signal (eg Faraday shield). For instance shielded audio cable remains unshielded unless grounded at one end. Does the same hold true for this foil barrier heat shield?

Any help will be appreciated.

Thanks,
Frank, K5OX

Other geologic events are passed via WX circuits besides earthquakes.
For example, ash plumes as detected by wx satellie observations.
NOTAMS are in the WX circuits.

When will CB have the same power and range as ham radio? When it does,
I'll go back.

CB is dead, quit using the term "CB" like an insult. It is short range
and therefore not a comparison.

Try to keep up. I have been quite consistent. You have not being
paying attention. I made no argument against voice at all. I made the
argument that a live voice conveys more than just words. Again, try to
keep up.

Never had a cat, did you? I grew up with them. They don't depend on
smell near as much as dogs but they depend on it just the same.

Are we on the radio right now? Your apples and oranges arguments are
getting tiresome. Here in Usenet, the text is preserved. CW is not.
Text on usenet is easily saved for future consideration. Is CW saved
on a radio server for others to listen to and reply to at their
leisure?

Don't be so obtuse. I NEVER said that I would get the proper
information. I said "SOME" information..look above. If I understood
Ukrainian then I would get the full message. If she spoke the same
words in monotone English then I would not likely grasp the degree of
anger at what I had or had not done.

>I can convey as much emotion in CW as your grandmother could in

Not a good analogy. I can still hear the CW. I just don't know the
meaning. Your analogy is more like trying to describe CW to a deaf
person.

>>>> Usent is text, by the way, not visual.
>
>>>I'll have to start using my ears to read your posts, then.
>
>>Raw data [text] is all that's needed for this conversation.
>

>Raw data is all that's available for communication.

With CW, yes. Raw data plus inflection conveys a fuller conversation.

>>You insist on reducing the term "communication" to just an exchange of
>>data. I am trying to point out that there is MUCH more to human
>>interactions than just data.
>
>There's much more to human interaction than lexical communications,

>else is totally irrelevant. You can't have any more than lexical
>communication by radio.

Oh bull! You get less than you can in person, true, but much more with
an angry or happy voice than with code.

>But tell bees that their dancing is just raw data. Then translate a
>bee dance for me, blind man.

This is relevant how?

Vocal communication is never just a conveyance of information but you
insist that's all that ham radio is.

Felix- your confusion is based on the fact that no one will believe you without a basis for a real comparison of your antenna with a reference antenna, done by another person, with publication of the results and a description of the method.
NO qso "data" will do this. In that regard, you are just another pusher of an EH or CFA antenna.
If you are serious, you will let some independent expert make one to your description, and test it properly. (That's what shot down the EH)
In regard to the inability of such programs as EZNEC to properly evaluate your antenna, I have not seen a well described antenna that could not be evaluated honestly by a person aware of antenna theory and the modelling programs.
Good luck-Bill

measure the VSWR at different frequencies in the 20m band, initially
VSWR should be quite high, and higher at the high end of the band;
> # shorten the line a little at a time and repeat from 5 until the VSWR minimum (should be
close to 1) occurs at 14.15MHz.

A nice article indeed. The above quote is from the set-up section. My
take is that this empirical approach requires almost no knowledge of
velocity factor at all. In fact, the article recommends against using
vf values listed or tabled in catalogs from suppliers. The reader is
instructed to find the vf ostensibly by experiment. This empirical
approach is the "old school" ham approach that I grew up with: cut and
tweak until you get what you want.

This is where we still live.

Owen, thanks for listing your article. Electrical length is indeed
important. Finding it by experiment is the process. I guess what I'm
trying to say is that, if you can't rely on published vf data and you
have to determine it empirically, you might be able to design a
perfectly good antenna, barely considering vf at all...just measure and
cut and measure and cut and...

True, not argument there.

> As for the "effect of capture area", the "capture area" of an antenna is
> just another way of stating the gain. This information is what you get
> from an antenna modeling program.
>
> Roy Lewallen, W7EL
>

What I had in mind is the difference in "capture area" related to physical
size of antenna like rhombic vs. similar gain, say Yagi. It appears that
rhombics perform better than corresponding Yagi thanks to larger physical
size (5 - 10 wave lengths) interacting with the environment (more like
diversity effect?). It seems that rhombics perform better than calculated
gain/capture area figures.
We will have opportunity to do some tests of rhombics farm vs. some classics
soon. It will be interesting to see the results.

Hi,

There are vast amunt of variety for 802.11 network adapter cards in the market.

For an experiement I am searching for 802.11x (a,b,g) adapter card with PCMCIA (or USB) interface.
This experiments will look at the RSSI (Rceive Signal Strength Indication), channel capacity (throughput), as a function of the range between two communication nodes, antenna type, polarization etc.

(A) Do you know any off the shelf 802.11x network adapter card with the following specs
* Software drivers for MS - Windows, Linux and QNX operating systems
* PCMCIA (or USB) interface
* RSSI (Rceive Signal Strength Indication)
* External antenna connection
(B) If you have you done similar experiments would you like to share your findings with us?

Regards

Miem Chan

Yes of course... but it is demoralising to recommend a procedure to people when it is not within the capability. They won't be happy sitting amidst a pile of chopped up ladder line and no result!

...
> Figure 2. (system losses) was a real eye opener! I enjoyed the article
>very much.

As a cross check, the G5RV's performance is easiest understood on 14MHz (where it is 3 half waves centre fed with a near 1:1 transformer to the coax) and 28MHz (where it is 6 half waves centre fed with a near 1:1 transformer to the coax).

Doing a back of the envelope calc for 14MHz where it is fed at a current maximum indicates ~90 ohm load on the coax, and VSWR ~2:1, so on the face of it, losses should be relatively low.

Doing a back of the envelope calc for 28MHz where it is fed at a voltage maximum indicates ~2100 ohm load on the coax, and load end VSWR ~42:1, so on the face of it, coax losses become much higher. Loss in 15m of RG58C/U under those conditions is ~8dB, or about 15% efficiency (coax alone). That reconciles with the graphs... the data is believable! (You could raise the coax efficiency with RG8X (as often recommended / supplied) to ~20% , but it still isn't pretty.)

Thanks Mike.

Actually regualr old 40/60 solid core works fine . the trick is the flux.
Use 10w motor oil. Over the years Ive won more than a few after work beers
from guys around here by soldering a copper wire to a pop top ring.

That's a commonly believed myth, but myth it is.

It seems that rhombics perform better than calculated
> gain/capture area figures.

So do EH, CFA, Isotron, Rai-beam, and more other antennas that I can count. That's because modeling programs just don't account for the magical effects.

> We will have opportunity to do some tests of rhombics farm vs. some classics
> soon. It will be interesting to see the results.

Maybe. Even fairly simple RF measurements are very difficult to make with even modest accuracy. Antenna measurements are more difficult yet.

> a higher class of license and increased privileges?

well, Dyslexia often affects the interconnection of the visual processing centers with that of visual pattern recognition. I know, I have that problem myself.

Since this problem appears to be one in the visual side of the system, it stands to reason that sound would not be affected in the same way (nor would touch - in my case, braille is far easier for me to read than the printed word was). CW is much the same way for me. I picked it up as a teen, but never did get around to using it, nor did I bother with it when I went in to take my first Amateur radio exame.

you may note how well I type. Actually, its an automatic spell checker correcting some of the "dyslexic typing" my fingers turn out. There are some word variations that still get past the spellcheck though. :(

point is, since CW is a sound language, it might be loads easier for her to learn than say the printed word.

I found time this weekend to construct this antenna and it seems to
work quite well. See <http://www.jedsoft.org/fun/antennas/omni.html>
for the details including a picture of the antenna.

While testing it, I made a contact through a distant repeater (40
miles away) and was told that the signal was solid. This was with the
antenna in its test position with the center about 10 feet off the
ground and the transmitter power at 5 watts. Unfortunately I cannot
be more quantitation than that.

Unless I have overlooked some other design, this seems to be an
extremely simple and effective home-brew antenna.

Comments welcome.
Thanks,
--John

Well Frank, you are in a bind if the in-the-attic antenna is all you can put up, especially for HF... The foil is an impenetrable barrier to RF trying to launch upwards...
How about loading the gutters around the house?
How about a flag pole vertical? Or even a pair for switchable end-fire / broad-side...
For a bit of money one of the pneumatic poles would make a great flag pole.. Down for 20 during the day and up for 40 at night...
How about a screwdriver tunable whip mounted somewhere on the center of the roof (if outside antennas are verboten you can call it a lightning rod), with the foil underneath and a few radials this should play...
Or as an angled "flag pole' off an upper window sill...
Maybe the wife would like a pulley clothes line for drying clothes - from the second story window? If it just happens to be a quarter wave on 40 meters the clothes should dry that much better...
(ya, ya, ya, I know you wet nosed kids don't have a clue what a pulley clothes line is - so expand your education)
How about a wire up the chimney? To a lightning rod?
As a last resort a wire can be run around the inside of the roofing insulation with a short screw into each sheet of foil board so it is all bonded... Then a vertical wire from the first floor, or the basement and load this as a vertical with a big top hat... You will need a good set of ground radials to work it against...

>
> Does anyone have any experience with this kind of attic. I have heard
> everything from it wont work to people that said it worked better than
> in other standard plywood attics.

The whole range of reports could be completely true. There are many variables involved, including but not limited to the width of the batts, whether and how much they overlap or how far they're spaced, how far and how they're oriented relative to the antenna, the type of antenna, the frequency, possibly the thickness of the aluminum, and the directions and elevation angles of desired communication.

So any binary answer of "works" or "doesn't work" has a 50% likelihood of being right. I generally use a coin to make this sort of decision.

> I thought a shield had to be at "ground" potential to effectively block
> a signal (eg Faraday shield).

Nope, not at all. To be effective, an RF shield has to be continuous, that is completely enclose what it is you're trying to shield. Shielding DC electrostatic fields is another matter and not applicable here. Your foil insulation makes a lousy shield at HF. But that's not to say it won't have some profound effects, as I elaborate below.

> For instance shielded audio cable remains
> unshielded unless grounded at one end. Does the same hold true for this
> foil barrier heat shield?

Nope. A shielded audio cable works somewhat differently than a coax cable carrying RF or an RF shield.

An HF antenna will be close to the foil in terms of wavelength. It will induce a current on the surface of the antenna side of the foil. This will flow around the edges of the foil to the outside, where it'll become the real antenna and radiate. The field from this conductor will (vectorially) add to whatever field escapes from the intended antenna

itself, so the net field will be a combination of the two. The only practical way to find out what the result will be is to try it. The proximity of the foil will also modify the impedance of the antenna, very possibly in a major way. So classical formulas for antennas in free space might be way off, and if so you'll probably need a tuner to match it.

What I don't know is whether the radiant barrier, which apparently is often much thinner than a conventional foil insulation moisture barrier and perforated to allow moisture through, might be thin and irregular enough to be lossy. But I kind of doubt it.

Good luck!

Uhhh guys, I hate to point this out to such an august group, but feel compelled...

The G5RV is well liked by the appliance operators because it works for them!!! (doh)

All right now, once you have quit swearing at the monitor screen and settled your ruffled feathers, ask me why it works... (Walt, please don't analyze the G5RV again, it has to cause pain and nausea when doing that.)

Simple, it works because it is unbalanced - and both the unbalanced top hat and the OCF feed line radiate... Bingo, instant communications, high angle and low angle... Does it work well?

Well, in a word, NO; not compared to efficient antennas... But the guys using it don't care (comprehend) that an efficient antenna (more time and effort) will give a 3dB or even 6dB better signal...

The other thing is the name has cachet... As in, " . . . the antenna here is a G5RV, that's George Five Radio VICTORY." Just as my generation took pride in, " the antenna here is an 8JK." (I am a cognoscenti and your antenna is dirt)

Now, back to our regularily scheduled program analyzing how many angels can operate CW on the head of a pin...

Roy, as a novice for Field Day it was raining cats and dogs... I went to the family farm out in the boonies and hung a 40 meter dipole the length of the barn, in the rafters and out of the rain..... Didn't occur to me that being about 8 feet under the metal roofing would be a problem... Well, even as a really green novice I knew when an antenna was a dog... That dipole couldn't even hear itself... And that is with the dipole being 35 feet in the air in the rafters... My Lafayette kit receiver (copy of an S-38, boy did those half circle dial indicators look cool) and a rock bound HeathKit DX-35... I froze my butt off in the milk house that night trying to make contacts... I don't remember the exact number but it could not have been more than 25 Q's... About 4AM I gave up and went back to town...

Frank,

Unfortunately, the results are very much of the "it depends" nature. A good friend in a condo with a similar situation does very well for short hops with a dipole and remote tuner in the attic, with some occasional DX thrown in on PSK31. With the "ground" so close, he is mostly seeing NVIS propagation into adjacent states. However, it is the only option due to the HOA.

He has one of those XM radios which can be used in the car or house. The only place it would work in the house was inconveniently near a window until he cut out a section of the insulation backing directly above the desired location. Works fine now.

Even the demo version of EZNEC, used judiciously, can do that.

The link below leads to a screen clip of EZNEC output windows. EZNEC parameters were set for the 1937 BL&E study for a 90 degree monopole, and the r-f ground produced by ~113 radials each about 0.41 lambda long

EZNEC shows an h-plane field of 189.76 mV/m at 1 mile for 1 kw of applied power. The BL&E paper shows about 191 mVm for those conditions (Figure 30).

The EZNEC calculation for these conditions differs from the BL&E paper by less than 0.06 dB.

http://i62.photobucket.com/albums/h85/rfry-100/BLE1937GroundSystemStudyNEC-2Emulat.gif

RF

PS: And many thanks to Roy Lewallen for making a demo version of EZNEC available.

Hi Roy,

This may be known only to people who live where the sun actually appears in the sky on regular occasions. What Frank is talking about is not ordinary foil-backed insulation batts. It is now very common in the South for the plywood sheeting used in roof structures to be completely covered with a bonded aluminum foil which serves as a radiant barrier. The only gaps are the small cracks between the plywood sheets. It is not the same as a completely solid sheet of aluminum, but the continuous aluminum pieces are much larger, and the gaps are much smaller than those that would be found in a typical installation of foil-backed insulation.

Your answer of "it depends" is of course completely correct.

Perhaps "myth" based on actual experiences. W6AM had a rhombic farm and
results in contests and comparison with locals using competitive antennas
seem to give it edge over calculations. I had rhombic once also and
experienced exceptional reports. I know it is anecdotal "evidence" but those
who used it, know the difference. Professional installations used them and I
have not seen them replacing it with the "same gain" Yagis.

I would not put rhombics in the same category, that is a stretch.
We saw the "infallability" of modeling programs using lumped inductors as
loading elements.

>> We will have opportunity to do some tests of rhombics farm vs. some
>> classics soon. It will be interesting to see the results.
>
> Maybe. Even fairly simple RF measurements are very difficult to make with
> even modest accuracy. Antenna measurements are more difficult yet.
>
> Roy Lewallen, W7EL

Very simple RF measurement is when comparing two antennas, one hearing the
signals, while another one is not.
One example at VE1ZZ: he has few beverages for Eu. Regular one, phased pair,
staggered pair and the "weird" one terminated on a stainless steel hubcap in
the salt water, very similar to the Regular one. The SS beats all the others
most of the time. They are about the same length ~870 ft, can the modeling

figure out wasaaap?

I am just trying to find excuse for seemingly superb performance of rhombics, attributing it perhaps to diversity effect by being stretched over large area. I am not selling any, but have access to about 30 of them over salt water marsh and will play with them.

161. Where Does the Power Go?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-02 14:34:04 UTC
From: Cecil Moore <mycall@hotmail.com>
Message-ID: <wr9Ug.7701$GR.4420@newssvr29.news.prodigy.net>
Source record: 51735

I've been told that this discussion continues in Letters
to the Editor in QEX magazine, to which I don't subscribe
any more. Without knowing the context of those present
discussions, I composed a letter to the QEX editors.
Here it is:

ï¿½Where Does the Power Go?ï¿½ was answered in my magazine article,
ï¿½An Energy Analysis at an Impedance Discontinuity in a Transmission
Lineï¿½, published by Worldradio magazine and available on my web
page at:

http://www.w5dxp.com/energy.htm

Here is a thought experiment that should lay the subject to rest.
Assume a one-second long lossless 50 ohm open-circuit transmission
line being driven by a 141.4 volt, 50 ohm Thevenin source. At time,
t = 0, source power is supplied to the transmission line. After one
second, 100 joules will have been delivered to the lineï¿½s forward
wave and the forward wave will have just reached the open-circuit at
the other end of the transmission line. What happens next simply
follows the laws of physics.

The conservation of energy principle tells us that the 100 joules
in the forward wave must be conserved. The conservation of momentum
principle tells us that the momentum in the forward wave must be
conserved. The open-circuit prohibits the forward wave from continuing
in the forward direction and the forward wave ceases to exist beyond
the open-circuit point. The forward wave ceases to exist so what
happens to the energy and momentum in the forward wave? Physically,
there is only one possibility.

The energy and momentum in the forward electromagnetic wave is moving
at the speed of light and is indeed conserved by transferring its
energy and momentum to the reflected wave at the open-circuit point
in accordance with the rules of the distributed-network/wave-reflection
model. This starts to happen at t = 1 second at which time 100 joules
of electromagnetic energy exists in the forward wave in the transmission
line. (One can actually calculate the force being exerted on the open-
circuit by the forward wave. It is akin to the pressure of sunlight.)

The transfer of energy and momentum from the forward wave to the
reflected wave continues throughout the t =1 to t = 2 second time
frame. At the end of two seconds, the forward wave contains 100
joules and the reflected wave contains 100 joules. Thus 200 joules
are "stored" in the transmission line during the first two seconds.
After two seconds, steady-state has been reached and the Thevenin

source ceases to supply any energy. No additional energy is needed since the system is lossless. But please note that 200 joules exist in the transmission line all during steady-state, exactly enough energy to support the 100 joules/second forward watts and the 100 joules/second reflected watts.

Any theory of where the energy goes must account for the 200 joules of energy in the transmission line. Those 200 joules cannot be destroyed by sweeping them under the steady-state rug. An ideal (lossless) directional wattmeter will tell us that forward watts = 100 watts and that reflected watts = 100 watts. 200 joules is required to support that number of forward and reflected watts. Is it just a coincidence that the 200 joules existing in the transmission line during steady-state is *exactly* the magnitude of energy required to support 100 watts forward and 100 watts reflected?

The number of joules in a transmission line is *always* exactly the number required to support the forward watts and reflected watts. Since EM waves cannot stand still, it seems logical to leave the energy right where it is at the beginning of steady-state - 200 joules per second being exchanged between the forward wave and the reflected wave. The energy exchanges at the two ends of the transmission line are balanced and equal so one might argue that there is no net energy exchange between the forward and reflected waves during steady-state. But since the two energy transfers are occurring thousands of miles apart, that would seem to be a moot point.

The transmission line is charged with this energy during the power on transient phase before steady-state is reached. The transmission line is discharged (energy dissipated) during the power down transient phase after steady-state. It is simply conservation of energy at work. It is interesting to note that if the transmission is discharged through a 50 ohm resistor at the far open-end, it will be discharged at a rate of 100 watts for two seconds.

With all due respect, Denny, where did you get your description of the G5RV--in Mad Magazine? Pardon me if I squash the new myth you just propagated.

The G5RV that I know of is not unbalanced, it has no top hat, it has no OCF feed line, and if there is a balun between the open-wire and the coax the feed line will not radiate. Seems like you've confused the G5RV with the psuedo-Windom, eh?

> More to the point, are there more licensed amateurs since the code requirement
> was removed years ago?

Yes. In the USA at least.

Since the inception of the no-code Technician class here in 1991,
the growth of the Technician class license numbers in the USA
has been continuous. Those now comprise about 49 % of ALL
licensees. The Technician class license numbers are twice that
of General class, the next-largest license class.

Since the "reconstruction" in FCC amateur radio regulations of
2001, the number of licensees grew to peak in July, 2003. At
that time the maximum code test rate was fixed at 5 WPM, all
classes.

A problem now is the attrition of the older licensees. More old-
timers are leaving/expiring (their licenses) than are being
replaced by new (never before licensed in amateur radio)
licensees. Source: www.hamdata.com. That trend has
persisted for three years.

The code test is not THE factor causing it, just one of the
major factors in slowing the increase of new licensees.
Coupled with the stubborn resistance to change of ANY
regulations by olde-tymers, there is little incentive to enter
olde-tyme amateur radio. Ally that with the huge growth of
the Internet in the 15 years it has been public - an Internet
that has spread worldwide with near-instant communications
over that world - and the traditional standards and practices
of olde-tyme ham radio just don't have the appeal to
newcomers they once had.

Elimination of the code test for any license will cause a spurt in new licensees. While such elimination is not a guarantee to far-future growth, it will be the significant act to being CHANGING regulations to better fit the modern times. Keeping up with changing times is a NECESSITY in regulations, regardless of the personal desires of the minority of amateurs making up the olde-tyme group.

True, although I did not put this on a weather circuit, but on the air
traffic control teletype network. We had both, actually.

Gosh Cecil... In a lossless line if you put in 100 joules, at the rate of 100 joules per second, and get 200 joules back, I predict that in less than 30 seconds (30 doublings) there will be a titanic explosion exceeding all the Hydrogen bombs on the planet... Do the math!

OK, tongue out of cheek...
Assume that we put a 1 second squirt at the rate of 100 Joules per second, into the input end of the line, it is an open line at the far end, and yank the input end of the line out of the transmitter at exactly 1 second... Now we have a lossless line with a wave going forward and a reflected wave coming back... Do you still claim 200 joules?

We are going to do this in quarters (25% of time, 25% of 100 joules and 25% of line length)
Start pushing energy into the line at T=0 and jump ahead to T = .25 second... The is 25 joules total in the .00 to .25 line section and 0 joules in the other 3 sections... At T=.50 there are 25 joules in each of the first two .25 sections and nothing in the last two .25 sections... Total 50 joules... The next two time periods is more of the same so let's jump to T=1.00
The line is now just 'full', with 4 'quarters' of energy having been inserted into the line, at that instant the leading edge of the wave reaches 1.00 of line (.25 x 4) and reflects off the open terminal, folding back and going towards the input... The total power in the line is 100 joules at T= 1.00.... No surprise there...
At 1.25 seconds we have a quarter of the wave reflected back and re-reaching the .75 line point (25 joules in that quarter) laid over top of the quarter of the wave front still going outwards in the .75 to 1.00 section (25 joules in that quarter).
So at T = 1.25 in that 0.75 to 1.00 portion of line we have 50 joules of energy (first quarter coming back plus second quarter still going out, passing each other...)
In the .50 to .75 line we have 25 joules of energy...
In the .25 to .50 line we have 25 joules of energy...
In the .00 to .25 line we have 0 joules of energy...

At T = 1.50 we have a wave going out in the .50 to .75 section and also in the .75 to 1.00 section... And reflected wave coming back in both those sections for 50 watts in each quarter section... The .00 to .25, and .25 to .50 sections are empty... For a total of 100 joules...

T=1.75 and 2.00 is just more of the same... 4 quarters of 25 joules each lined up a row with 4 quarters of 0 joules each... Chasing each other up and down the line, folding back and passing each other at each

.25 time period... A given quarter line section can have 0 joules, 25 joules or 50 joules, present at the instantaneous T of any given time block..

In a lossless line this power will slosh back and forth forever... Never having more than 50 joules in any quarter section of line and certainly not doubling to 200 joules... If you have ever held a slinky toy between your hands and watched the wave bouncing from hand to hand, you have seen what happens in the 1 second of line section...

BTW, this can be visualized by cutting 4 paper strips 3" long and marking them as 25 joules each and pushing them onto your 1 foot ruler (or ugly 250 mm stick) one at a time and just like box cars on a train see what they do...

Awww righty, now lets leave the transmitter on the line instead of yanking it... Sort of like non coitus interruptus...
At T=1.00 nothing is happening as far as the transmitter knows... The line is still taking power like a hungry calf taking milk from a cow...

At T = 1.25 we have put 125 joules into the line... The line section .75 to 1.00 is doubled up with 25 joules going and 25 joules coming...
At T = 1.50 we have put in 150 joules... Line sections 3 and 4 are doubled up to 50 joules each and line sections 1 and 2 have 25 joules each on board...
At t = 1.75 sections 2,3,4 are doubled up and only section one has 25 joules currently on board...
At T = 2.00 we have 50 joules in each quarter section of line for a total of 200 joules, and Cecil is fat and happy... Thinks he has been vindicated...

But wait! There's more... These Ginsu knifes will slice and dice and uuunhhh, - oops, wrong topic...
Well, as a thought experiment there is nothing to inhibit me from pumping another 100 joules into the line in the T = 2.00 to 3.00 time block, and again in the 3.00 to 4.00 time block, ad infinitum until we come to the Big Bang... So Cecil, why doesn't this happen? You can't have it both ways, a theoretical thought experiment of putting energy into a lossless line and at T = 2.00 suddenly revert to some mumble jumbo about the energy going away at the same rate it is entering, or the transmitter absorbing the reflected wave (those bottles gonna vaporize on the first long dah)... There is nothing in our theoretical world to differentiate T = 2 from any T = n + 1... Inquiring minds, and all that...

But let me suddenly play spoiler here... After 2 seconds, the reflected returning slug of energy present in each quarter line section is 180 degrees out of phase with the out going energy slug in each respective section... The two slugs vectorally neutralize each other... No energy present in that quarter section at any given T... So for each .25 T after T = 2.00 you are merely replacing the energy that has been neutralized by the returning wave.... Remember, energy can neither be

created nor destroyed... So, where did the energy go?

>Never had a cat, did you?

She's 7 years old now, and sleeping on my bed. Got her when her
mother died - she was still nursing - so, yes, I currently have a cat.
Have had some canine or feline pet since before I can remember -
usually more than 1.

> I grew up with them. They don't depend on
>smell near as much as dogs but they depend on it just the same.

They use it - about as much as we do - they don't depend on it.

>Are we on the radio right now? Your apples and oranges arguments are
>getting tiresome. Here in Usenet, the text is preserved. CW is not.

You're arguing for the visual now? Voice conveys more than CW, which
is your argument against CW. Voice conveys more than Usenet, which
ISN'T an argument against Usenet.

So which is it? Is the fact that voice conveys more than X an
argument against X or not?

I'm getting tired of your "I have to argue just so that I can win"
stance, so figure out how to get back to me when you grow up.

No, 100 joules/second * one second would be 100 joules in your
above example. In my previous example the 100 joule/sec "squirt"
was two seconds long. Thus, in my example, 200 joules made it
into the one-second long line.

> Never having more than 50 joules in any quarter section of line and
> certainly not doubling to 200 joules... If you have ever held a slinky
> toy between your hands and watched the wave bouncing from hand to hand,
> you have seen what happens in the 1 second of line section...

True for your example, but not true for my example. In my example
the 100 watt source was delivering 100 watts for two seconds. Last
time I checked 100 joules/sec * 2 seconds = 200 joules.

> At T = 2.00 we have 50 joules in each quarter section of line for a

> block, ...

On the contrary - if the frequency is an integer number of
cycles and the feedline is exactly one second long, the source
will see an infinite impedance after two seconds and further
sourcing of energy will be impossible. So I am ignoring the
rest of your posting until you understand that fact. Under
the stated the boundary conditions, it is impossible to shove
any more than 200 joules into the line.

At the end of two seconds, the forward current and the newly
arrived reflected current are 180 degrees out of phase and
cancel each other, i.e. after 2 seconds, Ifor + Iref = ZERO
The reflected voltage arrives back in phase with the forward
voltage and so the voltage at that point equals the voltage
in the 141.4 volt source and zero current flows between those

two equal potentials. There is 200 joules in the transmission line with no possibility of adding any more. The boundary conditions limit the energy content of the transmission line to 200 joules, exactly the number of joules needed to support the steady-state 100 watts forward and 100 watts reflected. The laws of physics strike again.

Please rethink your position.

Denny, as I just now looked SSE from my southern window I discovered a
near-field radiation from a OCF dipole, IDing with K8DO call sign. On looking up
that call I learned why that signal is in the near-fleld zone--it's only 26
miles away in the direction of light travel from my window. If K8DO was using a
balanced G5RV the signal would have evaporated before reaching Mt. Pleasant.
Ever hear of that town? Open yer NW window and yell, I'll hear 'ya.

Walt, W2DU

EZNEC can model radiating transmission line stubs made from either parallel wires or coax. To do it, parallel wire lines have to be modeled as wires, not with the non-radiating transmission line model. Radiating coax is modeled with a combination of a non-radiating transmission line model for the inside, and a wire to represent the radiating outside of the coax. This technique is described in the EZNEC manual and illustrated with the DipTL.EZ example file included with EZNEC.

There are some types of antennas which aren't possible to model with NEC-based programs. An example is a patch antenna on a dielectric substrate -- NEC and EZNEC have no way to model the dielectric. Likewise, a "loopstick" antenna -- a solenoid wound on a ferrite rod -- isn't possible because of the ferrite and possibly because of the exceptionally small dimensions (for one used at AM broadcast frequencies).

But most often when you see an antenna inventor or seller claim that his antenna "can't be modeled" by NEC, EZNEC, or other programs, it just means that modeling fails to show the extraordinary performance he claims for it. That's simply a failure of the program to include the effects of magical properties and wishful thinking in its calculations. I've come to regard such claims as a red flag indicating a probable exaggeration of antenna performance.

the big confusion factor is using power and energy at all. they are both derived from the much simpler to handle and understand voltage or current waves. the biggest problem is that once you change from voltage or current to power you lose the information necessary to calculate superposition because you no longer have the phase information from the basic wave components. this is partly a result of the common use of the swr meter that measures forward and reflected 'power', everyone thinks they understand how it works, but very few really do.

The problem with soldering to aluminum is that the aluminum oxidixes before it gets hot enough for the solder to stick. The trick is to puddle the solder on the aluminum, them using a stanless brush or something the solder won't stick to, brush the aluminum under the hot solder. That way the air can't get ot it to oxidize it. The solder will tin it and stick fine. I have been doing this since 1948.

You won't know until you try. A 20m dipole should be easy enough to get into any attic, and give it a shot. You might be pleasantly surprised, and that odds that you'll be terribly disappointed are pretty small.

It is spelled "prostate," but you did get "hemorrhoids" right. If you had to spell things via CW, you wouldn't have spelled only 50% of the big words right. I admit that you could use the Q signal for "How is your prostate?" (QYP?), but most good ops spell things out instead.

QYH?

I wish I had invented it, Jim, but the mechanism of wave
reflection due to interference was well known and under-
stood by optical engineers long before I was born. It's
how non-reflective glass works. Ideally, interference
at the thin-film coating reflects all of the light back
toward the picture behind the glass.

I wish I could remember the correct spelling for the antenna
I tried to model. Something like "Lentine". It is a dipole
of sorts made from shorted and open sections of balanced
transmission line. I tried modeling it with wires in EZNEC
and got all sorts of errors. It looked something like this:

```
+--------+--------+--------FP--------+--------+--------+
+------ +------ +------ ------+ ------+ ------+
```

Anyone remember the correct spelling for that antenna?

But it is hard to answer the "Where does the power go?"
question without using power and energy. BTW, I didn't
start that question. Jon Bloom asked that question in a
Dec. 1994 QEX article as a rebuttal to the information
in "Reflections", by Walter Maxwell.

> the biggest problem is that once you change from voltage or current
> to power you lose the information necessary to calculate superposition
> because you no longer have the phase information from the basic wave

If one knows the length of the transmission line and the
velocity factor, the phases can be deduced. If one is
dealing with a Z0-match, which is most common in amateur
radio, the phase information is trivial because all the
voltages and all the currents are either in-phase or
180 degrees out of phase at the Z0-match point.

>
>You're arguing for the visual now? Voice conveys more than CW, which
>is your argument against CW. Voice conveys more than Usenet, which
>ISN'T an argument against Usenet.

How many times do I have to tell you that I am not arguing against CW? It has it's place but I am arguing against CW as a requirement for full access to ARS. I ask what is so great about CW and all I seem to get is a rather patronizing "You wouldn't understand".

>So which is it? Is the fact that voice conveys more than X an
>argument against X or not?

This again shows how you have not been keeping up. Not an attack, an observation.

>I'm getting tired of your "I have to argue just so that I can win"
>stance, so figure out how to get back to me when you grow up.

Explain how I have to "grow up" and, while you are at it, explain how you are qualified to make such a statement. You have insulted me in such a manner several times yet I have said nothing of the sort to you. You patronize me while I give legitimate arguments. You don't like my arguments and try to deflect by misquoting.

Of all the pro-coders here, I had the most respect for your view. I didn't agree but at least you made a point without the typical insults of others here. Now you seem to be joining their ilk.

Sad.

What has been known since long before you were born is that only direct interaction with matter causes EM waves to reflect. You're far too modest Cecil. The "4th mechanism of reflection" is completely your idea! ;-)

Would you say the changing characteristic impedance between
two waveguides in outer space is a direct interaction
with matter? There is no matter inside the waveguide with
which to interact.

However, I am wondering if I am using the wrong word when
I say interference can cause reflections. Since the same
thing happens with scattering S-parameters, it may be
a 180 degree refraction instead of a 180 degree reflection.
I'll have to take a look at the math.

But no matter what it is called, the results are the same.

> idea! ;-)

Nope, it's not. The interference is caused
by the interaction of the forward and reflected waves
at a physical impedance discontinuity. The impedance
discontinuity is the primary cause of everything and is
certainly a point of "direct interaction with matter".
The reflection coefficients based on RF impedance
discontinuities are similar in kind to the reflection
coefficients based on differing light indices of
refraction between materials.

The forward reflection of light from a non-reflective
thin-film glass surface was well understood before I was
born. Optical engineers have no problem with that change
of EM wave momentum due to interference between the internal
reflection and the external reflection. That's the same
mechanism that happens at a Z0-match point in a transmission
line.

Google for "Lattin antenna". (Too many "lentils", Cecil :-)

One of the first hits is http://www.g3ycc.karoo.net/lattin.htm which shows a good sketch. The antenna is made from sections of 300-ohm ribbon or tubular feeder, configured as a string of quarter-wave stubs that progressively make the dipole shorter as the frequency increases.

The modeling challenge is that the ribbon operates in two different modes at the same time: a radiating common mode with a velocity factor of say 0.95; and a non-radiating "stub" mode with a VF of about 0.8. The problem is to model both modes simultaneously, for the whole string of stubs, without changing the physical dimensions of the real antenna. I'm not sure if NEC can do this, but maybe Roy can comment?

Hi Ian,

This "two different modes" is the magic mode factor that has not been
designed into EZNEC.

One need only look at the Lattin designs that "work" to discover they
violate the precepts of "how" they work.

Then note those that "should" work result in those don't work.

The bottom line is fairly obvious, but there are those who can 'splain
how its done (see magic mode factor).

No problem. Pipe the signal back from the far end into the shack, feed it into a circulator, and add it to the outgoing signal. Cecil will explain what happens to the power :-)

Replying to Yuri's point: from personal experience of using a rhombic 100 wavelengths long for 2m moonbounce, it had only about the same maximum gain as a box of 4 mid-size yagis - and that is only while the moon is passing through the very narrow main beam, which only happens for a magic 20 minutes on certain days of the month.

In other words, the rhombic did work, but the performance was nowhere near as spectacular as we had expected from its huge electrical length.

What is undeniably true is that it *looked* spectacular! I've used many kinds of antennas since then, up to an 85ft dish, but not one of them has given me the same buzz as that rhombic. And there is the trap: buzz isn't the same thing as performance.

We need to be very careful about applying dual standards. An unavoidable feature of all very long rhombics is that the main beam is very narrow, because the edges of the main lobe are sliced away by large numbers of sidelobes that are not many dB down. If we saw that kind of E-plane pattern in a yagi, we wouldn't hesitate to call it a "bad design"... so what's "good" about the same feature in a rhombic?

Hello, and Roy will probably want to weigh in here. What I can say is
that if you can create a wire model of the antenna consisting of
interconnected segments (ideally about 1/20 wavelength each) then NEC will
find the currents in each by considering all the interactions (conductive,
capacitive, inductive) between the segments. NEC doesn't care about the
geometry or "modes" of the antenna - it just sees a bunch of
interconnected segments distributed in 3-D space. There is no magic here
as NEC is merely applying text-book electromagnetic theory (you wouldn't
want to tackle this with just pencil and paper).

Once the individual segment currents are found (the time-consuming part)
It is relatively straight-forward for NEC to find the radiation pattern
shape, antenna gain and driving point(s) impedances. As with any
modelling program the trick is to make sure the wire segment model
adequately represents the actual/planned structure. Besides segment
length, there are a few other rules imposed by NEC that must also be
adhered to in order to obtain the correct results.

Roy is absolutely right in a previous post that an antenna vendor is most
likely blowing smoke by proclaiming that his/her antenna can't be modelled
by a method-of-moments program like NEC. (My favorite antenna "myth
busters" using NEC are Drs. John Belrose and Gerald Burke). Sincerely, and

That isn't a complete model of this particular antenna. The missing part
is the velocity factor of the twin-lead when acting as a stub, which
means that the electrical length of the stub is different from the
physical length. Which of those two lengths would you use in the NEC
model?

The answer is easy for a single-band model; but it's not so easy to
create one NEC model that will be valid for all the bands this antenna
is designed to cover.

Thanks Ian, for the spelling and for jogging my memory on the
subject. I believe you have hit the nail on the head. EZNEC
apparently cannot "model both modes simultaneously".

> explain what happens to the power :-)

Dr. Best, VE9SRB, in his 2001 QEX articles explained what would happen. Based on his idea that 75w + 8.33w = 133.33w, one could route the unused Rhombic power back to the source, recycle it, and cause voltage superposition to multiply the power up to a factor of 4. :-) To anyone who thinks I am kidding about Dr. Best posting the above equation, it can probably be verified by Google circa May 2001 on this newsgroup.

Dr. Best proved his assertions with the following power equation:

Ptot = P1 + P2 + 2[SQRT(P1*P2)]cos(A)

where A is the angle between V1 and V2. If we make the angle between V1 and V2 equal to zero, we can take the P1 power from the source and the P2 power routed back from the load and increase our total power output by a factor equal to 2[SQRT(P1*P2)]. Who says there is no such thing as a free lunch? :-)

Discussed by me in May 2001 was the fact that his term, 2[SQRT(P1*P2)] is constructive interference energy which must necessarily be exactly balanced by 2[SQRT(P1*P2)] watts of destructive interference energy or else the conservation of energy principle is violated. At the time, Dr. Best did not understand where the necessary destructive interference energy was coming from. It comes from the Z0-match between the feedline and the source and it works exactly like the thin-film layer on non-reflective glass. Dr. Best's Ptot equation above is true for A = 0 if and only if Ptot is being supplied with destructive interference energy where A is probably equal to 180 degrees.

The problem that EZNEC has with this antenna, as I understand it,
is that the same pair of parallel wires has common-mode current
in them on some frequencies resulting in a high VF and differential
mode current in them on other frequencies resulting in a low VF. I
don't know how to model changing VF's with EZNEC without changing
the physical length of the wires as frequency is changed.

Could a model be created for each band? What would be the
VF of the wire when 50% of the current was common-mode
and 50% of the current was differential mode?

Howdy Rhombic fans,

OK on Ian's rhombic experiences on V/UHF, but that I believe would be different situation, I.e. rhombic not working in conjunction with ground reflections/effects. With "normal" HF rhombic we have a situation where antenna is spread out over few wavelengths and interacting with ground.

Spacing two antennas few wavelengths can give us diversity effect by the virtue of propagation and waves hitting them differently. Rhombic is kind of antenna/feeders spread out over few wavelengths over ground. Perhaps there is also some of traveling wave mode going on, like in a Beverage. You can't simulate that or use VHF analogy being many wavelength away from the ground effects. Don't forget that skywave polarization is all over and rolling around.

I see big differences when trying to model vertical arrays destined to work on ground and modeled in "free space", different pattern and just plain ridiculous to do that. I know from my hardware experiments with Razors (quad - yagi) that if I changed height of the boom and I reoptimized the spacing/dimensions I would get different configuration. So my conclusion was that antenna has to be designed for the height it is going to be used at. Closer to ground, the more pronounced effect.

What I am trying to say and not sell anything, is that perhaps the ground effect and rhombic's spread over it over few wavelengths might have something to do with it's good performance.

I think that software modeling is a great tool, but I also know that it can not capture all the variables and effects that are happening around antennas, the ground and the sky.

All I am pointing out that based on mine and other's experience, rhombic is a great antenna, performing perhaps better than modeling shows (W8JI web site downplays it). If I get the chance, I will try to do some real life tests and comparisons on HF. We have some 30 rhombics, some phased side by side and will try to model and compare them with other antennas. BTW our rhombics have a load resistor made of open (resistive?) wire stub, folded few times back and forth. They were used with 50 kW transmitters.
see http://www.teslaradio.org/site_survey.htm

I am just trying to bring attention to possible discrepancy that perhaps is worth exploring. If some believe in gospel of modeling and paper antennas, than enjoy it. I prefer reality. When I wrote my observations about propagation happening by ducting and refraction some 25 years ago, I was ridiculed. Now the propagation experts are accepting it and playing discoverers (only ON4UN gives me some credit :-).

> I'll have to take a look at the math.

Cecil,

You may have taken the first step along the path to enlightenment. It has been explained previously on RRAA that interference is a result, not a cause. There are no primary equations related to interference that are useful for analyzing the exact behavior of a system. Sure, there are lots of handwaving explanations, but nothing that can actually give real numbers for fields, currents, or whatever.

If you start with the proper equations for the fields, or voltage and current if you desire, add in the correct boundary conditions on the interfaces, and then find the numerical solution, any interference will appear. No need to make a special case.

If you do this then two positive things will occur.

1. You will be in accord with virtually every mathematician, physical scientist, optical scientist, and even engineer in applying standard analysis techniques.

2. All of the worry about missing energy, canceling waves at the interfaces, etc. simply disappears. It all pops right out from the proper application of the math, automatically.

Yuri,

I am a bit puzzled by your comment. Ducting and refraction received a
lot of technical and mathematical study back at least to the mid-1930's.
Terman's books show similar figures to those in your CQ article, and
they give numerous technical references from the 1940's.

You may have been ridiculed by the amateur radio community, but the pros
accepted that sort of propagation explanation many decades earlier.

One dead, one arrested after CB radio argument at Vancouver mall

VANCOUVER, Wash. (AP) -- A Vancouver man was shot to death Saturday in the parking lot of Westfield Vancouver mall following an argument over citizens band radio.

Kenneth Eichhorn, 47, died after surgery at Southwest Washington Medical Center, police said Saturday. Jon William Loveless, 44, also of Vancouver, was arrested for investigation of second-degree murder in the shooting.

Police responded about 1:30 a.m. Saturday to reports of multiple shots fired in the mall parking lot. Officers found the wounded Eichhorn in his pickup truck.

Loveless called 911 a short time later, reporting that he had been involved in a shooting. He was being held without bail in the Clark County Jail.

The two men apparently did not know each other, but got into an argument over CB radio before they met at the mall. Both men were armed, police said. The nature of the disagreement was not disclosed.

Later Saturday, CB users were still talking about the early-morning argument between "Ken" and "Brander."

Longtime CB user Noel Perkins, 41, of Vancouver said he often hears arguments over the radio. "It's part of the game," said Perkins, whose CB handle is Snakebite. "Some people take it seriously, some people don't."

Back in the 70s a friend and I put up a rhombic antenna in a pecan orchard
on 11M. If I remember correctly each leg was about 8 wl long. At first we
thought we had done something wrong but then we began regularing talking
with guy about 45 miles away west of Tifton Ga.that we could not talk to on
his quad. Apparently the beam width is so narrow it makes it impractical
except for point to point comunication.

I've used lots of Dipoles in weird places and have gotten contacts. In low sunspot its not much
but your still communicating. I used an Inverted L next to a apt building from my 2nd floor apartment
and worked the world (High Sunspot time) :D. Remember, beams were not really in big use until the 40s.
Even then it took a while for it to catch on.

A question well stated, Slow Code...
No, it is a telephone conversation. Period. And that is what the whole hobby will turn into if the self-righteous, lazy whiners get their way and code is, once and for all, abolished. They all have contributed to the hobby's deterioration so far and don't like the fact that a few of us have got their number and can assess them for what they are. What do these simple-minded idiots think will happen if, as they press forward, they get all testing removed? The simple fact is that this is all a set up so the frequencies can be auctioned to non ham interests. The morons in Newington whimper about the reduced ham population. Geez Louise...there are many times more hams today (including those with the "faux" ham licenses not requiring code) than in the post WWII ham "boom." Not enough?

No kids...this whole code thing and the watering down of the test is simply a matter dividing and conquering so "they" can come in and tell us that our numbers don't justify the spectrum. Then...pfssssst!!!...there goes one band after another.

If any of the no coders had any balls they'd be asking the fcc for real testing and redevelop the hobby into what it used to be instead of the inane weekend contesting and buffoons sitting there are sideband comparing which rigs have the most features.

Idiots.

if you don't want to solder, just clean the aluminum area
and use a stainless steel hose clamp (automotive type)
with some noalox or similar anitox/sieze compound.

or deoxit on the area before clamping.

Hello, Ian. You would use the physical length for all wires that are interconnected and/or separated by free space. After all, that's what we're trying to model. You still must decide how many electrically-small segments would constitute, say, a 1 foot length of conductor. The higher the frequency, the more segments you will need. If transmission line is to be connected between segments, NEC has tools for doing that. BTW, my experience is with LLNL's NEC-4 (FORTRAN-77 source code) rather than the commercially-available packages. Sincerely,

Ian, GM3SEK commented thoughtfully on many points regarding the rhombic.

It is an excellent antenna for fixed point communications. Unfortunately, the earth and moon are not stationary with respect to each other. The rhombic may not be so re-directable as antennas like the Yagi or corner reflector.

For transmitting, the rhombic has a lower maximum voltage than a resonant standing-wave antenna. For high power, it`s a consideration.

The power remaining at the far end of the rhombic has been recycled by some to eliminaate waste.

Cecil does an excellent job of explaining where the power in a transmission line goes. Unfortunately, re-entrant rhombics tend to lose some of their advantages of simplicity and bandwidth in the elaboration process.

On the subject of diversity, it works by switching to a better receiving system. Without switching, spaced antennas only provide a phased array in which destructive interference happens during some signal conditions.

Where I worked, we used triple diversity receivers with 3 rhombic antennas spaced about 10 wavelengths apart at the low frequency end of the spectrum. A Crosby or Pioneer combiner selected the best of the 3 receiver outputs to feed a program line. Several receiving systems shared the same 3 rhombics for simultaneous program relay.

Sidelobes are only a small problem when using triple diversity and selectable sideband in reception.

Best regards, Richard Harrison, KB5WZI

Of course, the Big Bang is the cause of everything,
but what caused the Big Bang?

When one says A causes B which causes C which causes
D, etc., it is not false to say C causes D. There may
be a long line of causes and effects. One step's cause
is the previous step's effect. Interference causes
visible interference rings in a light experiment. And
of course, interference is just one event in a long
line of cause and effect. Without interference, there
would be no interference rings. Without beams of light,
there would be no interference. Without a Big Bang,
there would be no light.

In a line of events, interference is an event that has
a cause and has an effect.

The same is true at VHF. All rhombics interact with ground, because their length is many times greater than their height above ground. The number of wavelengths above ground will change the details, but not the basic fact.

Hello, Ian, and I guess I don't see how this is a problem provided you
have described the antenna geometry correctly and have chosen the
appropriate number of segments at the evaluation frequencies of interest.
Velocity factor and other electromagnetic phenomena are implicit in the
solution for the current distribution on the structure. Now, if
dielectric material is distributed in the structure that does complicate
things a bit. Can you point me to some further info on the antenna in
question? I trust this is not another one of those situations where there
is an attempt by vendors to "reinterpret" Maxwell's equations (or explain
things that Maxwell "left out").

I would encourage frequent users of NEC to subscribe to the mailing list

Agreed. I worked for an oil company on Tierra del Fuego. We frequently had no contact with our office in Buenos Aires. I put up a rhombic driven by a 20-watt Hallicrafters transmitter surplus from our Bolivian operations. They had upgraded to Collins 30-K5 transmtters there.

The Argentine Post Office used a surplus 300-watt BC-610 into a dipole near our camp. When I called the same station in Buenos Aires used by the Post Office, they at first would not believe that I was as far away as Tierra del Fuego.

Hi Ian,

This is simply a veiled expectation for EZNEC not being able to model
the "special attributes" of the antenna.

>The answer is easy for a single-band model; but it's not so easy to
>create one NEC model that will be valid for all the bands this antenna
>is designed to cover.

The answer is even easier than that. The Lattin antenna has a basic
rationale behind it that does not demand two different lengths: stub
tuning which is an electrical quality (not physical). What acts like
a stub, acts like a stub for any wire mesh modeling a stub. The
Lattin antenna does not exhibit this action to any correlation to
frequencies attributed to it. It is THAT simple. Appeals to physical
size relate only to the far field radiation characteristic. Even here
the Lattin is noted for being un-notable.

You don't need to worry about velocity factor, or dielectrics when the
basic rationale calls it a stub and it doesn't work as a stub for bare
wire. The Franklin antenna employs some of the same geometries and
nowhere makes a desperate grab for theoretical underpinnings called
stubs. Yet the Franklin delivers as promised if or when you add
dielectrics. The Franklin's simple distribution of currents (which
works for every antenna) works without having stray wires tacked on
like Irish Pennants. There are more apologists for this design than
working Lattins flying their tuning wires (in their notorious
disregard for the rationale of the design).

The fact of the matter is that modeling lays bear the myth.

Cecil,

You just proved the point perfectly. I did not say that interference is imaginary or that it is not a useful description. I said that interference is not a primary tool for achieving detailed numerical solutions. It is a result from such calculations.

Now put your hands down, solve the real equations, and stop all that mumbo-jumbo about canceling waves and reversing momentum.

Consider a folded dipole made from Wireman #562. The radiating
part of the antenna has a VF of 0.95 and the feedline has a
VF of 0.8. Identical wires with 19% different VFs. How does
EZNEC handle that?

Last things first - I just read John's later posting, and rescued this message from the out-tray. I hope this message will supply the extra detail you need, John.

Just one final thing:
>I trust this is not another one of those situations where there is an
>attempt by vendors to "reinterpret" Maxwell's equations (or explain
>things that Maxwell "left out").

Oh no. On that topic, I am an ironclad hardliner!

If you remember where we came in, Roy was mentioning a few types of antennas that it is acknowledged cannot be modeled with NEC-based programs. Cecil then inquired if the Lattin was one of those... and, subject to correction, I think it may be (if you require one model that covers all frequencies).

But every one of this small number of exceptions is for a clear and understandable reason, so they don't change the big picture, which is that "almost" all types of wire/rod antennas CAN be modeled accurately by NEC. If anyone thinks NEC doesn't work for their own pet antenna, the burden of proving that is entirely on them.

We now hand you back to the original reply...

J. B. Wood wrote:

Certainly... but most of this antenna consists of pairs of parallel wires that are physically interconnected, but are *not* separated by free space - the wires that are part of the twin-lead.

>You still must decide how many electrically-small
>segments would constitute, say, a 1 foot length of conductor. The higher

>experience is with LLNL's NEC-4 (FORTRAN-77 source code) rather than the
>commercially-available packages. Sincerely,

Sorry, that model still wouldn't work (unless I've misunderstood the principle of this antenna).

The whole point of modeling a multiband antenna is to get one model that is good for all its operating frequencies. That allows us to check that the SWR dips at all the right places, and to find out what's really happening in the supposedly "non-operative" parts of the antenna.

AIUI, the central part of the Lattin antenna is a half-wave dipole at the highest operating frequency - call it 30MHz, so the wavelength is a nice round number, 10.0m. Outside each end of this 5m long dipole is a quarter-wave stub made of twin-lead. These stubs are resonant at 30MHz, so they cut off the rest of the antenna (much like a trap) leaving just the central half-wave dipole as the only functional part at of the antenna.

The normal differential-mode velocity factor of the twin-lead applies to this stub, so its correct physical length is not a quarter-wavelength (2.5m) but about 0.8*2.5m = 2.0m.

Moving to the next lower operating frequency, there will be another pair of quarter-wave resonant stubs isolating the ends of a half-wave resonant dipole. But part of the physical length of this longer dipole is the 30MHz stub. If you model it at its true physical length of 2.0m, this will be correct for the lower frequency, but if you ignore the differential-mode velocity factor, the stub won't be resonant at 30MHz any more.

So the question remains: how can we model this "simplest" case of a two-band Lattin antenna, in a way that will be accurate at both frequencies? If we can solve that one, then extending it to the full 5-band Lattin should be child's play :-)

> Do you mean the mashed-potatoes energy equations where
> the wave energy components are completely ignored?

Calling the steady state solution "mashed-potatoes" is ridiculous. All other terms besides the steady-state ones have left the picture in the steady state. This is true of the waves, their amplitudes, the energy in the line, everything. That's what makes steady-state analysis useful... you can do it and be right.

If you want to know what happens during the transient, you MUST start from the original differential equation that describes how the fields were set up in the line in the first place, but it doesn't matter in the steady state. The answer is the same. If you start with the full, time dependent equations for turning the source on into some line, whatever it is that happens with the power and where it goes will become clear from the transient solution, which I know you haven't worked out. Neither have I.

I don't want to have to do it but one of these days I think it might be necessary.

This is not a problem that will be solved in with Logic and English, Cecil. There is no argument if you start with a full , time dependent mathematical description of the waves. That is what will answer the question "Where Does the Power Go" You'll end up with a time dependent Poynting vector that will tell you. I hypothesize, for no particularly good reason, that such a description will lead to the excess power having been delivered to the load through the interaction of the transient solutions on the line.

- - - - - -

Copied and pasted from the rest of my post at eHam:

In a matched line, none of us would disagree that the power flux out of one end of the line is the power flux into the other end.

>From what I understand, the electromagnetic energy contained in that line is related to the Poynting vector. The integral of the Poynting vector over the cross sectional area of the line gives you the time averaged power flowing in the line. The power flows at the group velocity of the waves in the line, for normal transmission lines, this is somewhere between 0.6 - 1.0 times the speed of light.

The power flow divided by the group velocity gives you the energy density per unit length in the line.

The power flow is the Poynting vector integrated over the cross sectional area of the line.

The Poynting vector in a mismatched line has been worked out by me, here, and I'd appreciate comments on the MATH.

http://en.wikipedia.org/wiki/User:Dan_Zimmerman/Sandbox

My claim is that that's it. That's all. No handwaving, no setting up steady state startup and claiming that that energy remains in the line. The real part of the Poynting vector represents real power flux and the imaginary part represents reactive power flux. To get the energy that exists in the line you just add it all up...

Take the real part, divide it by the propagation velocity on the line, integrate it over the area of the line (I think for TEM, the fields are uniform and so multiplying by the area of the line is sufficient)

This gives you the energy density per unit length for the power that's flowing from source to load. Integrate that over the length of the line. Set aside.

Take the imaginary part, do the same thing. This gives you the energy contained in the line of the reactive, circulating power. Add in the previously calculated energy of the flowing power, and you're done.

Am I wrong, Cecil et. al? If so, Cecil, could you please write down the description mathematically or get someone to help you out, and could you please look at and check my math?

I started with the assumption that there are two counterpropagating waves with some arbitrary electric field amplitudes and an arbitrary phase relationship. I didn't use anything about Thevenin. I didn't use anything about virtual open circuits.

The forward and reverse waves have been included, from the beginning. They're both there.

When the SWR is 1:1, there is no energy in the line associated with reactive stored power. None at all. The reflection coefficient is zero, and all energy in the line is associated with flowing power.

When the SWR is infinite, there is no energy in the line associated with flowing power. None at all. The reflection coefficient is 1, and all energy in the line is associated with circulating power (reactance only, as you would expect from a stub)

Dan

The pressure of such a momentum change can be calculated.
From "Optics", by Hecht, 4th edition, page 57:
"When the surface under illumination is *perfectly
reflecting*, the beam that entered with a velocity
of +c will emerge with a velocity of -c. This
corresponds to twice the change in momentum that
occurs on absorption, and hence,"

Pressure of a absorbed wave = S(t)/c

Pressure of a reflected wave = 2*S(t)/c

I'll bet the reason no one can measure the radiation pressure
resulting from your "4th mechanism of reflection" is because it
cancels out with the radiation pressure from the cancelled reflection
in the other direction. Right, Cecil? :-)

Hi Jim,

Who needs reasoning when a Xeroxed formula, like a "4th mechanism of
reflection," is simpler to cut and paste than actually offer a
practical answer to? This is akin to his sophomoric allusion to
anti-glare coating yet again (yawn), he couldn't work the math on that
one anywhere closer than pi = 22/7.

Soon we will be down the path of 66% allowable error to prove a
concept.

There is certainly radiation pressure pushing outward
from a 1/4WL thin-film non-reflecting surface even
though the reflected waves cancel each other.

wrote:

>Richard, I wasn't the one who, through superposition of powers,
Yes, you did have a problem translating power to energy and back. I
could offer any number of common scenarios that would have you gasping
for air:
There is a common bare light bulb 1 meter away;
it illuminates a cmï¿½ target with 3ï¿½W @ 55nM of POWER;

what is:
the number of candela per steradians,
at the target,
from total bandwidth radiation?
or:
How much power is being supplied to the bulb?

>came up with an irradiance brighter than the surface of the sun
>at the non-reflective surface interface.

No, true to your form, you rounded errors and fudged numbers to prove
light was black.

In that regard I will offer you a third choice question from above:
Can you see this amount of light on the target?
(choose this one, you might guess it right - it doesn't demand any
math skill.)

265. Re: Antenna Theory

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-03 19:04:28 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <12i5d1u4k9h8oba@corp.supernews.com>
Source record: 51589

If made from twinlead with insulation between the conductors (e.g., window line or 300 ohm flat or tubular TV twinlead), NEC based programs can't model it exactly in a straightforward fashion for the same reason it can't model patch antennas on a substrate -- the program can't account for the effect of the dielectric between the conductors.

The two modes Ian speaks of can be separated by separating the two currents into common and differential modes(*). The common mode current is the source of all the radiation. It propagates as Ian says at a relatively high velocity factor. This mode is modeled quite well with EZNEC or NEC-4's insulated wire feature.

The differential mode current doesn't cause radiation. Its velocity factor is determined by the dielectric between the wires, and NEC-based programs don't have any way to account for the field modification which the dielectric causes to bring this about. That's where the shortcoming is.

The net result is that the radiating properties of the stubs can be accurately modeled, but their length which determines the "trapping" or loading characteristics would be off. Of course, such an antenna made from air-insulated twinlead could be modeled easily.

I've successfully modeled a folded dipole made with TV twinlead by physically separating it into common mode and differential mode structures. The common mode portion is a simple dipole, with diameter equal to the effective diameter of the two conductors in parallel, and with wire insulation. Then across the feedpoint I put non-radiating transmission line models to model the differential mode transmission line stubs. The lengths of these took into account the twinlead velocity factor, and their impedances were 1/4 the impedance of the real stubs because of the transforming property of the structure. The result was a good model, provided that the feedpoint impedance was multiplied by 4.

A first look indicates that this approach wouldn't be practical with the Lattin, because it would require large jumps in effective wire diameter as you go along the antenna, which NEC doesn't handle well.

What you really need is a way to increase the differential mode length of each of the stubs without impacting the common mode length. A few quick sketches indicate that it just might be possible to insert a transmission line model (which has no physical length or common mode radiation) in series with a stub, which would accomplish the goal if its length were made to equal the difference between electrical and physical length of the real stub. But I don't have time to pursue it. Anyone interested in doing so should begin with a single stub and carefully observe its characteristics.

Whenever modeling close spaced parallel wires with NEC-based programs,
it's vital that the segment junctions be aligned on the wires. There's
more information about this in the EZNEC manual (available also with the
demo program). Look in the index under "Parallel Wires".

(*) Modeling programs don't treat the modes separately. But separating
them makes it easier to explain and understand what causes the problems.

As always, Ian put his finger directly on a fundamental principle.

The problem with modeling programs is that they don't model the buzz.

Please don't deliberately obfuscate things, Gene.

There are no reflected waves on the outside of the
thin-film and therefore no reflected wave pressure
from the outside.

All the reflected waves are on the inside of the
thin-film outer plane. That's why the reflected wave
pressure is pushing outwards.

The pressure is where the waves are. There's no
wave pressure without waves.

NEC-based modeling programs don't have any problem simulating a Beverage
and its traveling wave operation -- they do quite well at it.
MININEC-based programs, no longer in wide use, weren't able to because
of the use of perfect ground during impedance and current calculations.

>> the wave energy components are completely ignored?
>
> Calling the steady state solution "mashed-potatoes" is ridiculous.

I'm not calling the solutions ridiculous. I am calling some
of the conceptual conclusions ridiculous. For instance, since
the *net* Poynting vector equals delivered source watts, there
are zero watts in the reflected wave even though there are
joules in the reflected wave moving at the speed of light.

> If you want to know what happens during the transient, you MUST start
> from the original differential equation that describes how the fields
> were set up in the line in the first place, but it doesn't matter in
> the steady state. The answer is the same.

Not according to some of the gurus posting here. The joules
supplied during the initial transient state are being swept
under the steady-state rug. Witness "Food For Thought #1"
on www.eznec.com

> I don't want to have to do it but one of these days I think it might be
> necessary.

What you will find is that there is exactly the energy in the
transmission line required to support the real speed-of-light
forward traveling wave and the real speed-of-light reflected
traveling wave - no more and no less. The argument that there
is no more energy in a transmission line with reflections than
is being supplied by the source is simply false.

> The Poynting vector in a mismatched line has been worked out by me,
> here, and I'd appreciate comments on the MATH.
>
> http://en.wikipedia.org/wiki/User:Dan_Zimmerman/Sandbox

What about the forward Poynting vector, Pz+, and the reflected
Poynting vector, Pz-. Reference page 291, "Fields and Waves ...",
Ramo and Whinnery, 2nd edition?

> My claim is that that's it. That's all. No handwaving, no setting up
> steady state startup and claiming that that energy remains in the line.
> The real part of the Poynting vector represents real power flux and
> the imaginary part represents reactive power flux. To get the energy
> that exists in the line you just add it all up...

The forward wave's average Poynting vector is real. The reflected wave's average Poynting vector is real. Adding two real power flow vectors is a lot easier than integrating a power flow vector with real and imaginary parts. And, bottom line, one obtains exactly the same results with 10% of the work. Subtract the reverse Poynting vector from the forward Poynting vector to determine the net power. Add the two Poynting vectors and multiply by the length in seconds of the feedline to determine the total energy. What could be simpler?

> Am I wrong, Cecil et. al?

No, you are correct but you are going around the world to get from California to New York. My method, supported by Ramo and Whinnery, can be done in much less time and can be more easily understood by people not familiar with your method. By the time you get out your calculator, I can have your answer waiting for you and it will be the same answer you get after wasting a lot of time.

> When the SWR is infinite, there is no energy in the line associated
> with flowing power. None at all. The reflection coefficient is 1, and
> all energy in the line is associated with circulating power (reactance
> only, as you would expect from a stub)

You are, of course, talking about *net* "flowing" power. But your answer is exactly the same as component forward power in real joules/sec plus component reflected power in real joules/sec. And thinking in terms of those real component powers is a lot easier than your imaginary stuff.

Pz+ - Pz- = Pz-tot sourced and delivered

(Pz+ + Pz-)* feedline length in seconds = total feedline energy

There is also a physics problem with the imaginary concept. EM wave energy must necessarily move at the speed of light. A small amount of TV modulation will prove that those forward and reflected waves are still moving end to end at the speed of light and still transferring information.

Actually I agree, but it's all from ordinary reflections, rather than
from backscattered interference or anything else from the 'square root
of negative one' axis.

Have to agree-- aluminium oxidizes almost
immediatly, when burnished, and as mentioned
the trick is to get the solder to the aluminum,
before it re-oxidizes . As an aside, the silvery
powder in a firecracker IS powdered aluminium,
which gives an idea of how FAST the stuff oxidizes
(burn, in this situation)! Jim NN7K

Turned out that under power the center conductor of the matching network
embedded in the top main section of the antenna migrated through the dilectric
and shorted to the sleeve, thus making the lower and mid matching rods "hot",
and effectively changing the antenna from a vertical loaded dipole to a random
length vertical ground plane.

This is a Hustler Colinear Two Meter Fixed Station Antenna Model G7-144 in fine condition for $80. This was the premier two meter antenna and probably still is with it's phenomenal gain. It has been in my garage for a good number of years after being up for a short period of time. Except for a touch of rust on a couple of the clamps, the antenna is super clean. I can send pictures showing this and a scan of the original docs if desired.

Having to disassemble the antenna for shipping is too much of a problem for me at this time (I'm 75). Consequently, I am offering it for sale under the market value. I'm located in Westfield, NJ, just five minutes off exit 135 of the Garden State Parkway

Hello, Ian and I think the problem here is with the dielectric in the transmission line. As I said earlier, the presence of dielectric material in the structure does complicate things. NEC AFAIK was never intended to handle this situation. I wouldn't say that NEC couldn't model this antenna but it would be a challenge. And as you point out a NEC wire model of this antenna not accounting for dielectric effects would be incomplete at a given frequency. I have never tried to model an antenna with NEC that included dielectric material nested between wires. Sincerely,

Hi John,

EZNEC has the capacity to model wires with insulation. I presume that is a legacy of NEC, but I will await tutoring on that point from other posters. Carry that a bit further, it has at least "some" capacity to model wires with material nested between them. After all, the difference is in degree, not in concept, and the degree is hardly remarkable. When I observe common window line, it is not all that different from two insulated wires. Further, there is nothing remarkably different to the degree that the Lattin analysis is so entirely thrown off as to be wholly useless. For that matter, I haven't observed any postings here on any Lattin analysis other than my own. If this all hinges on TV type twin lead, then too much credit is being given to too little plastic.

Yes, they are much better as HF point-to-point antennas than they are as general purpose. For that kind of service, you can pick your height and rhombic size to specifically service the one path.

yeah now that i had a chance to check some manuf spec's seems the
losses they post for the regular rt angles looking like 2 pipe pieces
mitered and the 'square' ones seem to have same loss .1 etc 11gig

and are <less ten bucks

the swep ones i saw were rated to 18gig wow and like 150bucks loss
and swr were about the same but from the very high end atten was
best

obv i don't have any first hand exp so i am not disagreeing

i know when i've had the chance to test connectors in the past
sometimes you did get some really dissapointing results

I built one of these, and it didn't seem to actually resonate very
sharply anywhere. It certainly did not work as advertised.

I ended up with a lot of ladder line pieces to make 2m J poles with
though, so not a great loss.

Anyone need a J pole?

In almost fifty years of hamming I never had an antenna
that was anywhere near ideal. For many years I couldn't measure let alone
spell SWR! I tied the wire onto the output of the pi-network and
never considered antenna tuners. I thought the cold water pipe was great and all
I needed. My antennas were too high, too low, or tilted the
wrong way. Most were bent around corners, and resembled
the fractal. Propagation let me think that if I got the signal into
the air it would bounce around till I made a contact. If I heard
someone I could usually work them. The RF burns were thrilling, and
told me that I had output! I fired my arrows into
the air and never ceased having fun. Ignorance was bliss. If
I'd known much about antenna theory I'd still be working on the plans
instead of on the air!

If we raise the CW speed to 20 WPM for all classes including the Tech class, hams will tend to study the theory more while they build up their code skill and they will understand the theory better and won't need to ask silly questions. So increasing the speed requirement will get us better & smarter hams.

Lazy people that don't want to learn anything will stay on CB and die in shoot-outs with each other in shopping mall parking lots which will help clean up the CB band. To me it looks like a Win Win situation. What do you think?

Jim, the reflected energy and momentum changes direction.
Walter Maxwell calls it a virtual short or open with a
virtual reflection coefficient of 1.0. I agree with "Optics",
by Hecht, that it is total destructive interference in the
source direction accompanied by total constructive interference
in the load direction. What do you call it? What reflection
coefficient does your reflected wave see? Please give it a
name.

Although it's a feature of NEC-4, it's not part of NEC-2. The insulated wire capability of EZNEC was developed independently from other sources.

> Carry that a bit further, it has at least "some" capacity to
> model wires with material nested between them. After all, the
> difference is in degree, not in concept, and the degree is hardly
> remarkable.

No, they're different things. The insulated wire feature slightly modifies the field from a wire, and is valid only for thin insulating layers. Insulation between conductors has a considerably larger effect on the field and consequent coupling between them. Adding insulation to a parallel wire line gives you a model of something like an air-insulated ladder line made with insulated wire.

> When I observe common window line, it is not all that
> different from two insulated wires.

It's enough to drop the differential mode velocity factor down to somewhere around 0.91 - 0.95 (from various sources - I haven't measured any), which indeed isn't very different from the common mode velocity factor of insulated wire. Whether or not the difference is significant depends on the application.

You could probably make a model with EZNEC which would be fairly close, then manually adjust it to optimize performance. A real antenna would have similar performance if optimized for the type of line it's constructed from, although the final dimensions would be a bit different.

Simply not true, Tom. For a Z0-match, the phase is always
zero or 180 degrees. Only addition or subtraction is
ever required at a Z0-match. I've got the answer while
you guys are still trying to figure out the cosine of
zero degrees. :-)

Hi Roy,

And insulated wire is different from wire insulated by window line
insulation?

>Insulation between conductors has a considerably larger effect
>on the field and consequent coupling between them.

? Insulated wire HAS insulation between conductors. Air certainly
qualifies to some degree, the insulation on the wire another.

>Adding insulation to
>a parallel wire line gives you a model of something like an

That makes sense only in that it repeats the obvious. How is
insulated parallel wires (air-insulated ladder line made with
insulated wire) different from window line? Or twin lead? Except by
degree?

>> When I observe common window line, it is not all that

This is not a very compelling argument for how Lattins WORK (seeing as
most reports suggest they do not). It is not a very compelling
argument for very remarkable differences in where they do work
(however, few seem to be offered in that regard either).

Quite simply, velocity factors do not explain away the lack of
resonance ANYWHERE near the intended frequency. What you suggest is
percentages where actual performance misses the target, not just the
mark and as a multiband structure is so wildly useless as to be a
product of chaotic, random doodling.

Having modeled more than a few Lattins (and there are so many as to
beg the definition), any claim to resonance associated with a stub
dimension FOR ANY "ELECTRICAL LENGTH" is a fantasy of the first order.

The inability to model a working Lattin has no basis in these
arguments about the shortfall of EZNEC/NEC insulation issues. The
antenna design fails quite abysmally for bare wire when designed to
the purported rationale of trapping by stub construction. To think
the design can be resurrected by unmodelable insulation tricks is
based on hope and charity.

I think the 5/8ths is much more practical on 50 than the 1/2
wavelength. You will find the matching unit much easier to build. The
down side is you have to have radials.

As far as I can tell, Terman describes ducting and refraction relating to UHF. This was well known in VHF/UHF circles and I mention that in my article. What I tried to point out that this is also happening at the HF frequencies, down to 160m.

The closest thing would be Pedersen ray, but that seems to describe relatively short refraction in the layer.

All the literature I was familiar at that time showed distorted pictures of Earth and exaggerated height of layers and "bounces".

I assumed that your VHF rhombic was perhaps high and maybe even rotatable.

I do not have measurements and evidence, just anecdotal evidence using one, hearing from other users and based on some comments on the subject and experiencing some discrepancies with modeling, just speculating that there is something to it. If all those who never used rhombic, but modeled its performance and are convinced that that's it, then I rest my case.

I will have chance to run some test and will report, if it doesn't annoy K0TAR.

Hi Yuri,

I have a couple of refraction citations made by Ladner and Stoner in
"Short Wave Wireless Communications," 1932. They dedicate the book
to C. S. Franklin.
"Refraction may produce an appreciable increase in signal strength
at longer distances and can be expect to produce fading effects
similar to those experienced with the longer waves from the
ionosphere."

How this is achieved conforms to classic ducting, although they
neglect to call it such:
"Under certain conditions theoretical curves are available
from which the field strength at an elevated receiver,
produced from an elevated transmitter, may be deduced."

No Roy -- The intended lesson is that you don't have to
wait until you can learn enough theory to understand the antenna
before you stick a wire into the air. Get on the air first -- then
start learning. Why sit there with a ticket to play, but be
afraid because you don't know all the rules of the game yet.

Why do you want ham radio to be like CB then by dumbing down exams? Or
are you just saying that because you're a typical lazy-ass Kanadian that
believes everything should be a government hand-out with no work required?

And half a century ago those VHF/UHF hams had passed a code test. They
weren't no-coders, they were motivated and did what it took. Today's
no-codes aren't motivated and don't want to make an effort, therefore
they're probably not going to be motivated to move things forward either.

Do you have any idea how really stupid you sound? You keep on
repeating this "dumbing down" mantra like it actually means something.
Newsflash. Ham radio and CB are really only different in the range
available. Ham is just CB that goes further and there is nothing you
can do to change that.

And, for the 15'th time, the no-code test here in Canada is TOUGHER
than the code test.

>Or
>are you just saying that because you're a typical lazy-ass Kanadian that

You seem pretty knowledgeable so I need some assistance at
understanding something.

What I can't understand is the the incredibly childish attitude of
some of the pro-coders here. For me, the confusion stems from having
known several old timer hams while growing up. I looked up to them.
They were older gentlemen that had some fascinating knowledge and
great stories to tell about their ham radio hobby. This was back in
the 60's and early 70's so they are all gone now.

I am sure now that they are spinning in their graves, after the spew
puked up by some of the pro-coders.

Not all of them, to be fair, but a few loud ones stand out.

I still can't figure out how a statement about how CW is just beeps[
as opposed to voice on the same hardware] became transmuted into a
requirement that I should hate usenet.
That kind of blatant mis-direction seems to be quite common.

The statement is quite simple...a voice on the airwaves can convey
much more information than just the words spoken but CW can only
convey the words. Since the medium and usually the hardware is exactly
the same weather or not a microphone or a key is used, why bother with
a key that is much more limited? Somehow, this relates to pixels on my
screen but I have yet to understand why my opponent felt the need to
misdirect, misrepresent and misquote. Can none of the pro-coders make
a valid point?

Why do some of them feel that insulting my daughter will make their
point valid? Are their points so weak that they resort to vulgar
insults instead of engaging in debate? I usually don't killfile people
but I have made a few exceptions lately.

Now, there will be some spew directed towards my post. They can go
ahead and prove that turning ham into CB will most certainly be a
great improvement to the ARS. I NEVER knew anybody on CB that was as
rude and vulgar as some of the pro-coders here. I can have a nasty
mouth too, at times, but it's always in response to stupidity that is
obviously not to be taken seriously.

And, ironically, *I* am the one told to grow up. That's just too
funny.

Actually, the Technician License was offered with
reduced code requirements for hams who were more
interested in technical experimentation than in
ragchewing.

347. QTFTWWAC

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-05 11:38:12 UTC
From: Denny <k8do@mailblocks.com>
Message-ID: <1160048292.525389.290460@k70g2000cwa.googlegroups.com>
Source record: 51671

Another chapter in my decades long 'quest to find the worlds worst antenna configuration' (QTFTWWAC)...
This weekend I hurled into the air another conglomeration of consisting of three pieces of ugly bent, used wire.... After tree branches, bird droppings, and gravity did its thing I wound up with a bottom fed, half lambda vertical for 40 meters, with a pair of elevated radials... The bottom of the antenna is 7 feet up, the 2 radials slope from there to about 3 feet...
Being that the antenna analyzer had dead batteries (my magic fingers left it on again), I tuned the matching network by the method I learned as a lad, putting a brick on the key I went out to the antenna and using a pencil to draw an arc off the wire I tuned the cap for maximum sparks... Trudged the hundred yards back to the shack and plopped down in front of the radio... Quick check showed swr to be 2.8:1 at the bottom of the band rising to 1:1 above the top of the band... In my youth before swr meters this would have been a raging success...
Anyway, the swr a bit too much for the amp at 7005 kc so I ran the Omni barefoot getting about 70 watts out... The band was weakly open into eurasia... FIrst Q was a UA3, then a UA9, followed by by G, DL, EA, EI, etc., for a round dozen DX Q's in about 40 minutes...

OK, so this antenna is another dismal failure in my QTFTWWAC, don't use this antenna configuration if you want to be able to hold your head up in polite company... If you do go off into the weeds <don't smoke em> and decide to use it, a few more radials will get that last dB, or so, out of it... Christman finds a round dozen elevated radials to be the sweet spot between improvement and vanishing returns... Now, that work was done for quarter lambda verticals which need the ground as the antenna image, so it may not translate directly to a half lambda vertical which is a balanced monopole... Here the radials mostly keep the coax from getting too friendly with the antenna, and partially screens the night crawlers from a sunburn...

The intent is to do FS measurements with 2, 4, and 8 elevated radials to see if this configuration responds differently than a quarter lambda... Yesterday I went out in the meadow with the 706 and a battery in a garden cart... I tuned the parallel network for 1:1 at 7050kc... The antenna covers the whole band at less than 1.5:1 without retuning... In testing I called a quick CQ and had a w4bkd/m come back to me... He's an OT like me, but said this was the first time he worked someone standing out in a field, up on a ladder, with the radio clamped under his arm, holding the paddles in his hand, in the rain... I surmised that given my usual mental state that this was pretty much SOP for me...

Dunno if I will get to the radial tests... This week end it has to come down so the highly secret 80 meter arrays <complete with decoder ring in the box> for CQWW can go up, as I continue on the trail to the holy grail of the QTFTWWAC...

Denny, I don't know what you do for a living, but you could make millions as a standup comedian, unless you're having someone else write your material.

Deterrming SWR by measuring the length of the spark at the end of the dipole is hilarious. On the other hand, I don't believe you'd have enough energy left at the end of a hundred yards of feedline to even develop a spark there.

But that's neither here or there--let's get down to specifics--why are you ignoring me? We're so close together in Michigan that we could QSO with smoke signals, as I pointed out in one of my posts on the thread concerning the G5RV. And did you not receive an email from me? I know my attempt at humor doesn't begin to compare with yours, but I thought at least we could become acquainted, so why are you ignoring me?

Walt, W2DU

351. Problem with off topic postings in antenna newsgroup

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-05 15:24:59 UTC
From: ricknj10@hotmail.com
Message-ID: <4525196a.10903484@news.optonline.net>
Source record: 51675

I am sure you all have been experiencing the recent onslaught of off topic postings in the antenna newsgroup. Subjects such as CB, code, etc. Character assinations, childish BS. What follows is an idea I have to combat this foolishness. I am dead serious about this. If you are interested in participating, read on.

It happens when someone initiates a posting and "cross posts" it to multiple newsgroups including rec.radio.amateur.antenna. They do this because they think they reach a wider audience, instead of confining their subject to the appropriate newsgroup (such as, possibly, rec.radio.amateur.policy). They really aren't too smart and they don't have any manners or or appreciation of netiquette at all. Then what happens is someone sees their posting and decides to add their 2 cents worth, and they just use the default list of newsgroups which was included in the original posting, and voila! their reply also goes to 6 different newsgroups.

I have an idea to rid us of this littering. Take an off topic posting, do a reply to it, be sure to edit your posting so that it DOES NOT appear in the antenna newsgroup. This is vital. In your reply posting just post a simple one line message, something like "I agree" or "yeah, right on Dude." Do it as many times as your energy lasts. (It would not hurt to edit your reply email to some bogus address so you do not get flames).

Now, when someone in another newsgroup sees the offending thread, they will begin reading it, and see dozens of useless messages (all those "I agree, Dude" messages). Remember, these replies are not showing up in the antenna newsgroup. After someone has read 50 of them they will get the message. If they choose to do a reply, remember they are not smart enough to know better, their reply will only go to the newsgroups which you have left in place.

Ok? Agree? Pick the next crap, off topic posting you see and fire away, along with me.

Rick K2XT

Hi Rick, Sounds like an idea. The moronic trash is certainly irritating.
My answer is to add all such postings to my "Blocked senders" list,
and I don't see it anymore. I just have to watch that I do not add
Richard Clark, and others, who sometimes respond to the postings.

Regards,

Frank

That the reflected wave(s) have reversed momentum is a fact
since at one point they are measured as photonic energy
traveling toward the source and at another point they are
measured as having disappeared. Remember, these are photonic
EM waves. They necessarily must travel at the speed of light
or not exist. The photonic component waves in non-reflective
glass all travel at the speed of light. In like manner, so
do the photonic component RF waves in a transmission line.
Photonic EM waves don't change their basic nature with frequency.

You still didn't give me a word for that change in momentum.
Walter Maxwell calls it "re-reflected". I would be satisfied
with "re-directed' or "momentum-reversed". What would you
like to name it?

While you are at it, you never did give me a word for watts
that are not power.

What's to keep the same low-lifes from replying, "I agree
too, Dude", and re-directing it back to r.r.a.a?

"Subjects such as CB, code, etc,"

Some insist CB is an "either-or" relationship with code. The FCC has assigned space for both. Amateur radio operators have imagined their own problems.

The "Morse code forever" characters are nearly all retirees hanging on to an obsolete mode now replaced by other digital modes and analog communications. The U.S. military abandoned Morse long ago. It hangs on in the imagination of some unreconstructed "coots".

I`d like my grandchildren to have fun with radio and not bother with Morse. "You don`t make people learn how to ride a horse before they drive a car".

Barbarians are riffraff whether coded or not. They have no reason to leave the internet.

Because they are clueless to how Usenet works. The message they are replying to is NOT in r.r.a.a, it is now in some other newsgroup, and there are let's say, 50 of them, so many that it is an annoyance to even read through them. So when they finally have had enough after reading 10 of the 50, they decide to reply, their stupid reply will only go to the newsgroups that are in the message they are replying to (which does NOT contain r.r.a.a). Ok? Got it?

Indeed, the major offender - the one who has extreme spelling challenges, knows exactly what he is doing. He keeps multiple addresses to avoid posting limits, and if you reply to his messages in a manner in which he disagrees with, you'll get replies from all of 'em.

The wonderful people involved in this are branching out from their usual newsgroups because they aren't getting the attention they crave there. Most of the old regulars are gone from rrap, and if there isn't anyone to fight with, it ain' no fun, man!

If you do use your tactic, which does have some attraction to it, you might want an anonymizer.

>You seem pretty knowledgeable so I need some assistance at
>understanding something.

Jim, that statement is bound to ignite more flame war
stuff in here, heh heh heh heh heh...

>What I can't understand is the the incredibly childish attitude of
>some of the pro-coders here.

Part of that is the Nature of the Beast, the computer-
modem mode of communications. The 'Beast' got 'steroids'
with the ability to send 'anonymous' messages (they
think...traceability is possible but only through
systems administrators' access to the 'Net). When that
happened the early male adolescent behavior surfaced
with all its immaturity.

Having participated in computer-modem communications
locally and networked since December 1984, I've seen
quite a bit of that. It is clinically, also morbidly
fascinating to me. Since most of my early experiences
were on local BBSs there was the opportunity to meet
socially with those participants, get real clues to
the person instead of just seeing their words on a
screen. In most their words echoed their up-close
personnae. In perhaps a quarter of them their
fantasies and imaginations ruled their screen words,
their public, social interaction being nowhere near
that and they were relatively subdued, few having
'remarkable' lives. It could be said that their
computer-modem personnae represented their
imaginations given a pseudo-life, something to
fantasize about to relieve their everyday lives'
frustrations.

With the ability to be anonymous (through some 'Net
servers) those imaginations and frustrations can be
let out full force. The 'anonymous' ones become
aggressive, 'in-your-face' types, no longer mindful
of normal social, in-person behavior rules. This is
aided by the relative isolation of time and distance
of messaging. The aggressive ones need have no fear
of physical confrontation as a result of their words,

they can act 'tough' or abusive or insulting in
safety. Ergo, many found emotional 'relief' in the
filthy venting we've all seen in just this newsgroup.

It's a not-nice condition in some humans to have
their (usually suppressed) anger, frustration,
bigotry so close to the surface but it does exist
in them. It can turn to rage and action in rare
cases, thus the stories of violence that show up in
the news. Humans aren't perfect by a long shot.
Civilization requires a greater suppression of that
internal rage, anger, frustration for the common
good but some think internally that they are 'better'
than the common folk. Hence we get the overtones of
'superiority' through sub-groups in which their
capabilities are exaggerated in those groups' self-
righteous descriptions of themselves.

That isn't confined to amateur radio. It exists
all along the human experience.

>For me, the confusion stems from having
>known several old timer hams while growing up. I looked up to them.

Understandable from the viewpoint of younger people. I
think we've all had such experiences...mine were scarce
in regards to amateur radio in my hometown but there
were lots with other life experiences that were fun to
listen to and to respect.

>They were older gentlemen that had some fascinating knowledge and
>great stories to tell about their ham radio hobby. This was back in
>the 60's and early 70's so they are all gone now.

Being of a younger age, my growing-up days 'old
timers' were rather focussed on the experience of
World War II. "Radio" per se was seldom mentioned
as a part of that.

What is most interesting (to me) is finding out later
that some of them were exaggerating what they said
and a few were downright liars! :-)

If one survives long enough to become the same age
as those 'old timers' (in a relative chronological
way that is), it is easier to see where they are
coming from! Much easier...! :-)

>I am sure now that they are spinning in their graves, after the spew
>puked up by some of the pro-coders.

Well, if the afterlife allows such observation of
mortals, I'm of the opinion that those old 'old-timers'

are having a good time and laughing at the mortals'
shenanigans!

>Not all of them, to be fair, but a few loud ones stand out.

The loud ones stand out because they MUST stand out
and make everyone pay attention to them. Their EGO
demands it. They want to RULE, to control, to judge,
to be in-charge. In here those are confined to the
pro-coders or who USE their tested morsemanship
(however long ago that happened, if it ever did)
to show "how good" they are.

>I still can't figure out how a statement about how CW is just beeps[
>as opposed to voice on the same hardware] became transmuted into a
>requirement that I should hate usenet.

Not surprising to me. Those fixated on their alleged
superiority dispense with logic, go emotional, and
become one with the rabble, the filth-spewers. They
are NOT interested in anything but making themselves
look good to themselves on their own screens. They
have little recognition that the same 'message' they
sent is read by anyone else but the recipient...when
it may be read by thousands of others who never reply.

>That kind of blatant mis-direction seems to be quite common.

I agree. Such misdirection is common on just about
every newsgroup, has precedence in the BBSs, even on
the old ARPANET just before it morphed into USENET.
Lacking the validity of anything but their own
experiences, they toss logic out the window and
consentrate on 'conquering' the message thread.

>The statement is quite simple...a voice on the airwaves can convey
>much more information than just the words spoken but CW can only
>convey the words.

You know that, I know that, and hundreds of thousands
of other humans know that. That's the reason that
all other radio services except amateur radio have
dispensed with on-off keying radiotelegraphy for
communications purposes. At least in the USA; I
don't have enough information about Canada's use of
communications modes to verify that.

>Since the medium and usually the hardware is exactly
>the same weather or not a microphone or a key is used, why bother with
>a key that is much more limited?

Logic in such an argument is NOT desired by pro-coders.
They are fixated on the medium, not the message. They

got their rank-status-privileges mainly through their morsemanship and their egos demand that Their desires should be those of all.

Part of that fixation on radiotelegraphy in the USA is a result of the tremendous amount of ham-oriented publications of the ARRL. The ARRL emphasizes radio-telegraphy as the ne-plus-ultra of amateur radio skills. Since the ARRL has a virtual monopoly on amateur radio publications here, has had that for at least seven decades, they can and have managed to condition the thinking of American amateur radio licensees in favor of radiotelegraphy.

Those who've been conditioned will not understand that they've been imprinted but insist it like some 'natural order of things.' Further, they tend to out-rage and the very idea that they've been brainwashed! Such outrage takes on a religious fervor at times.

>Somehow, this relates to pixels on my
>screen but I have yet to understand why my opponent felt the need to
>misdirect, misrepresent and misquote. Can none of the pro-coders make
>a valid point?

Few can. In here I'd say that NONE can.

Your 'opponent' wasn't trying to argue logically. Klein was obviously using emotion as an 'argument,' frustrated at not being able to 'triumph' in a message exchange.

>Why do some of them feel that insulting my daughter will make their
>point valid?

It is an emotional ATTACK ploy. It is common in nearly all newsgroups. Those that do these sort of things can get away with it, unworried about any direct physical confrontation that might ensue.

>Are their points so weak that they resort to vulgar
>insults instead of engaging in debate?

Yes.

>Now, there will be some spew directed towards my post.

Of course...and to this reply. One can 'take that to the bank.' :-)

>They can go
>ahead and prove that turning ham into CB will most certainly be a
>great improvement to the ARS.

Well, the expressed bigotry against CB by hams is a very
old thing going back to 1958 when the FCC created "Class
C and D" CB service on an 11 meter frequency band de-
allocated from amateur radio use down here. Having to
work both with and for some old-time hams, I heard mostly
howls of outrage and indignation that the FCC 'dared' to
take away 'their' band and 'give' it to 'civilians.'
Worse yet, NO TEST, not the slightest requirement to
demonstrate morsemanship in order to use an HF band! :-)

> I NEVER knew anybody on CB that was as
>rude and vulgar as some of the pro-coders here.

I have to agree with you. The vast majority of CB use
down here is on highways, mostly by truckers but a large
number of RV-driving vacationers are there, too. At
worst, some trucker might go into a long tale of some-
thing (that only a few consider funny) but I have yet
to hear outright personal insults on CB. I quit
using CB mobile in late 1999 after selling my '82
Camaro but a twice-a-year fire-up of CB at home doesn't
indicate anything different; this residence in southern
California is only a half mile from our Interstate 5,
a major highway north-south near the Pacific coast. Our
cell phone now works so well on major highways that we
don't have any consideration of installing any other
radio in our present car.

>And, ironically, *I* am the one told to grow up. That's just too
>funny.

Well, that's how it goes. :-) Expect more of that
kind of comment. I dare say it will occur under
'moderation' as well.

When a pro-coder says "grow up," they really mean "think
like I think, appreciate only what I like, etc." They
use that little throw-away line in lieu of a personal
insult, a button-pushing phrase to get their 'opponent'
angry. Sometimes it works, but most of the time it is
just their stupid way of attempting retaliation.

not sure Mike if you are refering to me but thank you i do know what I
am doing OTOH you do not

tell me how did you moderated to death effort to rep[lace RRAP go
did you learn when you surpess desent you kill discusioons of issues

I never added radio NG to posting never I lleave as is since if I am
libled in the post I want the response to go to all of them I was
libeled in

prehaps mike is you had foucsed your anager on theose using slibel and
chrater assignation years ago instead of tolerating and rewarding it
things would not be so bad

but of course NOTHING is your responsiblity even in part

In addition to the problems others have pointed out, following this advice would result in our spamming other newsgroups. The folks at most of the other newsgroups are just as annoyed and not to blame as we are, yet we'd be adding to their QRN. How would you like it if the folks on one of those newsgroups were to do the same thing you propose? I'll add that the mental- and maturity-challenged people making these postings thrive on attention of any kind, and even meaningless responses confirm that their postings are attracting the attention they crave.

I don't have a solution for it, any more than I have a solution for spam. I've developed ways to deal with over 200 spams a day, and if this gets too much out of hand, I'll find some way to deal with it too. A Thunderbird add-in allowing plonking all cross-posted messages or ones cross-posted to certain other groups probably wouldn't be too difficult, and would provide relief for Thunderbird users at least.

In the meantime, it comes with the territory, like mosquitoes in the woods and roaches in cheap hotels. It's sad that people can reach physical adulthood without advancing beyond that level of maturity, but it's a fact of life. And we've got to keep working around it and not let their inanity push out the people wanting to talk about antennas. But I don't agree with this suggestion as a way to fight it.

Absolutely not ignoring you Walt... Your name is certainly known to me... Shucks I have been reading my pablum stained copy of 'reflections' for years... I have to say it is tough sledding when one reads by sliding his finger along the print whilst making lip movements... Could you have used shorter words, say less than one syllable, for folks like me - especially the preface?

Now, on the pencil tuner - scouts honor on the facts I posted - if you think the end of a half wave antenna won't bite, try it! From the color of the burns on my finger I would say that it was at least 1834z +/- j1571...

I did not see an email from you in the inbox... Nope not spoofing my email, but it may be an outdated one... Current Email address is:

ad4hk2004@yahoo.com

Give me a buzz... I just dropped a note to Arch Doty on the counterpoise topic...
I'm leaving the office now 5:10 pm... Won't see any replies until tomorrow am... Going home to cruise the bottom of 40 meters...

cheers ... denny / k8do

Yes, Some people are lazy and as long as there is a CW requirement they won't go for a ham license, or upgrade beyond tech. They don't really want to be hams enough to put out an effort to be one, but the ones that go for the CW and written exams really want to be hams, and will stick with the service and will be an important part of keeping it going.

Do you have a spare tire in your car in case you get a flat tire? Ham radio without a CW requirement is like driving your car around without a spare tire. Why do you people want to dumb everything down all the time.

Eliminating CW is a loss in the number of ways we can communicate.

> So, should momentum change? Or should we expect it to be conserved?

Momentum is conserved. A change in momentum is a change in
the direction of momentum, not a change in the magnitude.
Hams call that a reflection. What do you call it?

> I still like "Cecil's 4th Mechanism of Reflection" best.

If you don't like the word "reflection" for what happens at
a non-reflective thin-film coating, please give me another
word for it. I could easily call the physical happening by
another name. "A rose by any other name ..."

> Ask again after you've come to understand the difference between a unit
> of measurement and a defined physical quantity.

Jim, in engineering, all watts are power. That's an engineering
convention. I'm sorry that your physicist conventions are different
but amateur radio is part of RF engineering. Sorry about that.

So is your claim that, to "hams", a change in the magnitude of
momentum is not called a change in momentum?

Actually an antireflective coating does not reflect energy. Hence the
name. If I had to give it a name I guess I'd call it an
anti-reflection. Howz that?

I get it that you're sorry. That wouldn't be rhetorical sorrow by any chance, would it? As I said, please let us know when you come understand the difference between units and physical quantities. I don't need to give you the energy in 25 candy bars divided by the number of minutes in a regulation NBA game example again, do I?

Source record: 51558

Korbin,
I have just done a heap of experimenting on 80m using a Terlin Outbacker "Outreach" mobile whip.
I found that it made none or little difference when using 4 x 1/4 wavelength radials.
I then used a 33 ft fibreglass extendable pole with a dipole attached, certainly and naturally it outperformed the mobile whip.
I made up a full wave loop on 80m, slung it vertically between 2 large trees, and found it out performed the dipole, mainly because of the noise level was lower than either the mobile whip or the dipole.
On receive the full wave loop was the best, followed by the inverted vee and lagging way behind was the mobile whip.
my 2 cents worth.
John

Since when was talking as in Phone SSB not
"communication". Sure code is fine, but most of
us learned to key "mama" long after we learned to
say it ;)

I know the comment about people leaving Amateur radio isn't Barrys comment,
but thought I'd address it anyway. I was 69 when I got my Tech license and
72 by the time I made myself pass the code test and got my General. A lot of
the avid pro-morse Hams are even older than I am. I know of no one locally
who has just quit the hobby and those senior to me are not leaving
on their own at all, when they do stop Hammin' it's 'cause their keys went
silent. I never used code after passing the test. I've got the thought in
the back of my mind that I may sometime
pursue a little CW, but it all depends on when I get my own SK notice.

Folks

So I'm reading the 2006 ARRL Handbook page 22.6, There is a single line stating "Steel wire is a poor conductor at RF; Avoid it." Any idea why? Or is this just one of those physical properties?

So how much poorer than copper? Steel clothesline is easily obtained and not that expensive. Admittedly though I haven't done much research on copper or the other type of wires the Handbook mentions.

Hi Tony,

Go ahead and use steel clothesline, it will work fine.

Source record: 51566

Steel has a resistivity many times that of copper. It varies a lot with the alloy, so it's not possible to put a single number on it. But the real problem is that steel is ferromagnetic -- in other words, it has a high permeability.

At radio frequencies, current flows in a thin layer near the surface of the conductor. (It actually continues clear to the center of the conductor, but the density decreases very rapidly with depth, so it's essentially zero anywhere except very near the surface.) This concentration of the current has the same result as passing the current through a wire of much smaller cross-sectional area: it greatly increases the resistance of the path carrying the current.

The problem is that the thickness of this layer (more technically, the rate at which the current density decays with depth) is determined by, among other things, the permeability of the material -- the higher the permeability, the shallower the layer. So the higher the permeability, the higher the resistance. The permeability of steel is probably even more variable than resistivity, but I'd be surprised if you ever found any in common use with permeability under 100. Or if you found some with permeability of several thousand. Since the relationship between the depth of current flow and permeability is a square root, this means RF resistance of 10 to 100 or so times that of copper, as well as the higher resistance due to the higher DC material resistivity.

If the antenna has a large enough surface area, even steel is fine. A common example is an FM mobile whip, which has insignificant loss, or a tower operated as a vertical. But because of the way the current depth and antenna size change with frequency, the loss with a given wire size gets greater and greater as you go lower in frequency, assuming the antenna stays the same size in terms of wavelength. So while moderate diameter steel wire might have insignificant loss on the higher frequency HF bands, that same wire might have substantial loss at the lower end of the HF range.

Most hams can measure SWR, but almost none can quantitatively measure the strength of the signal their antennas radiate. And most run way more power than needed to communicate, so can easily lose quite a few dB without a major effect on communications. Consequently, the wider bandwidth gained due to loss in steel wire is considered an asset, while the few dB loss is probably not noticed. (Although hams spend a staggering amount of money trying to buy a few extra dB of gain. Go figure.) In fact, I recall an article some years ago -- in QST if I'm not mistaken -- featuring a wide-band 80 meter antenna whose secret was just that -- loss from using steel wire.

If you try it, you might just like it!

By the way, copper wire is easily obtained and not that expensive,
either, should you choose to go for a stronger signal rather than wider
bandwidth.

Hmm. OK, how about talking to a no-code with a yet-to-be-activated
General? I sat for & took the Tech, passed and they mentioned I could
take the General. Great. Passed that one as well. Working on Morse
now.

Missed the Extra, though, by a few questions.

Was my first shot at any exam.

Neither a Tech nor a General makes one a Ham, though.
Nor Morse.

That only qualifies you to be a good student of the avocation.
I don't expect to be really good at ham radio until I've played
around
with a transceiver for a year or two, maybe. Still need to learn
the lingo,
learn electronics, get my feet wet, build a receiver and maybe a
transmitter,
blow up a few caps..you know, OJT. Plus lots of hamfests where I'll
be looking for a cute hamette.

When I finally DO get a rig of some kind, I sorta kinda might be
Ready
for going after QSOs.

Even from folks who think I've got an honorary degree.

> anti-reflection. Howz that?

You must have one of your special tricky-dicky narrow-
minded physics definitions for "reflect" like you do for
"power" and "transfer". It is a fact that the internal
reflection is reflected at the outside surface of the
thin-film. Constructive interference energy due to wave
cancellation joins that reflection energy and becomes
inseparable from it. It has been commonly called a
reflection (actually a re-reflection) for decades.

> As I said, please let us know when you come
> understand the difference between units and physical quantities.

Please let us know when you come to understand the difference
in definitions between two technical disciplines. Unfortunately
for your definitions, amateur radio is a subset of RF engineering,
not physics. You may, in time, succeed in your quest to change
the definitions previously accepted as valid in the field of RF
engineering. Then again, you may not. Time will tell.

That's looking forward into a Z0-match from the source
side. The opposite thing happens looking back into a
Z0-match from the load side. What's the opposite of
an anti-reflection?

Actually, in my energy analysis article, I defined
the word, "re-reflection", as used in the article
and as used by Walter Maxwell in "Reflections".

Since I cannot find an official definition of that word,
defining it within an article is a perfectly honest and
acceptable thing to do. Quoting my article:

"Note that the author is defining the word "re-reflection"
as any and all reversals in direction of flow of reflected
energy or reflected energy components."

My energy article can be accessed at the URL below.

P.S. I'll be in HOG heaven during the long weekend.

Roy,
As my cobwebby brain remembers, for conductive materials such as aluminum through gold, the rough rule of thumb is that at 10 megacycles the skin depth is .01MM (01 is 10 backwards, only reason I remember) So 1mm is 0.0394" therefore a skin depth of 0.1mm is 0.00394", call it 4/1000 of an inch for round numbers... So, the other rough rule of thumb I have always used in my wasted career in industrial electronics is to have the conductive plating 5 times the skin depth... So, 0.020" would suffice for 10 megacycles...
Now, that begs the question for steel, or zinc plated steel... Anyone interested can google up answers with a bit of personal effort...

What has always intrigued me though, is the concept that a moving charge at RF frequences, spreads over the surface and penetrates only 0.020" the majority of the charge (@10 mc) , while still having lines of flux penetrating radially to the electrical center of the metal object... Yet, by the same token, if the metal shape is a hollow tube, no signal will be detected upon the inner skin of the tube...

I think you dropped a decimal point, there, Denny. How did you get
from 0.01mm skin depth at 10MHz to talking about 0.1mm? If you stay at
0.01mm, it would be about 0.4 mils. The rule of thumb I remember is
2.6 mils at 1MHz, so it would be 0.8 mils at 10MHz. That's for
copper and as Roy wrote, steel will be much less.

Another rule of thumb: the RF resistance of copper wire is about 1
milliohm/foot * sqrt(freq. in MHz) / diameter in inches. For 14AWG
wire at 4MHz, that's about 31 milliohms per foot, which is pretty much
inconsequential for a 75M half-wave dipole with about 75 ohms feedpoint
radiation resistance.

The resistivity of nonmagnetic stainless steel is roughly 50 times that
of copper, so the loss would be about seven times as great at RF,
assuming that the permeability really is low at RF; that wouldn't be
bad. But high permeability would not be good, especially in a small
diameter wire..

Moderately wide bandwidth, high strength, low loss dipole: a center
support steel cable, surrounded by 4 or so small copper conductors in a
"cage" spaced out from the center support to make a conductor perhaps
1/200 of a wavelength effective diameter.

Cheers,
Tom

Cecil,

Where you go wrong is your energy analysis. Your argument goes awry in at least a couple of areas. 1. 'destructive interference causes energy to reverse direction.' This is purely false. Interference is the description we give to the result of the superposition of waves. It is not a causal phenomenon. 2. Unless you're talking photochromic properties, partially reflective media interfaces do not become 100% reflective in response to illumination (or for any other reason). Any "re-reflection" that takes place is ordinary partial reflection in the other direction.

Have fun on the hog. Last weekend I was fortunate enough to drive 20 laps on a 1/2 mile banked track in a Busch class stock car. Holy cow.

Differences between disciplines in the definitions of fundamental
principles can only be in your understanding of them.

Come on, Cecil. You propose a scenario with a change in
characteristic impedance, and then try to pretend there isn't any
matter involved?

Sorry, Jim, for responding through you to these howlers courtesy of
Cecil's Xerographic talents.

Producing "all" electric "and" magnetic fields? This is just too
naive to contemplate. I suppose our compasses don't work in the dark,
do they? A light bulb would never illuminate unless it was ALREADY ON
illuminating the wire that conducted electricity.

The list of amusing contradictions to this catechism above goes on,
and on.... Now we return you to Cecil's lamentations about the
quality of work he puts to the copier's scanning screen. :-0

Imagine, cribbing notes from and then blaming Wikipedia indeed!

> : step upward in performance.
> :
> : Mobile antennas have very low efficiency, grounding them will not improve
> : that significantly relative to the dipole.
> :
> : KD

Efficiency doesn't even come into play in his case, being he is only
worried about receiving. As far as voltage to his radio, he already
has
more than enough with the mobile whip as is. As one mentioned, the
s/n ratio is what matters. And going to a larger vertical is likely not
to
help at all. Even switching to a dipole would not be an improvement
unless the signals are coming from higher angles, etc. IE: 75m NVIS..
There are cases where my mobile antenna outperforms my home dipoles.
But these will be cases where the distance, etc favors using a
vertical.
So anyway, the short of it is adding radials to the mobile will not
help receiving at all. And switching to a larger antenna is not likely
to
help either unless there is a reason such as a horizontal dipole
favoring
NVIS. All but the puniest mistuned receiving antennas have enough
voltage
to get an acceptable s/n ratio from any decent radio. It's like adding
a tuner,
etc to a random wire. Unless there is a specific reason for it, it's a
waste
of time in most all cases.

Jim, when I get back from my trip, I'll tell you about temporary
benign interference Vs permanent active interference. A standing
wave in a constant Z0 environment is temporary interference.
Wave cancellation is permanent active interference. When wave
cancellation occurs, the energy and momentum are redirected. In
a transmission line, there are only two directions. In the direction
of the wave cancellation and in the opposite direction. The energy
doesn't go in the direction of wave cancellation so which direction
does it go. Boy, that's a tough question, isn't it?

> Have fun on the hog. Last weekend I was fortunate enough to drive 20

Back when I lived in CA, in between motorcycle races, they opened
Laguna Seca to anyone with a motorcycle license, street legal bike,
$20, and willing to sign a waiver. Everyone was a certain number
of minutes apart. I got my Kawi Z1-B up to about 135 mph on the

straightaway. And that still wasn't top speed. That machine red-
lined at 60 mph in *first gear* with four more gears to go. :-0

Any 12 year old can learn code in 2 weeks. Getting rid of it would not
dumb down Ham radio at all. Code is a good thing to know. Whether you
use it or not is a personal preference. I think programming you're own
software to send code yourself and building your own radio is a lot more
technical than learning code.

Please realize that it's not the definitions of fundamental
principles that are different. It is the definitions of the
random grouping of letters called words that are different.
The same word represents different valid fundamental principles
in different disciplines. "A rose by any other name ..."

Physics simply does NOT have a monopoly on the word "power".
There are 32+ definitions of power in my dictionary.

P-O-W-E-R has a different definition in RF engineering than
it does in physics. It doesn't mean that there's anything
wrong with anyone's fundamental principles. After all, the
Russians and Japanese don't even use the word "power" for
any of their fundamental principles which are just as valid
as yours.

If you are admitting that a change in Z0 at an impedance
discontinuity involves matter, then we are in agreement.
Sounded to me like you were saying there's no matter
involved at a transmission line impedance discontinuity.

My energy article covers this subject. I state in that article
that there are no reflections except at *physical* impedance
discontinuities so you already know what I said previously.

Roy, W7EL wrote:
"---the loss with a given wire size gets greater as you go lower in frequency,---.

Effective resistance to r.f, is approximately proportional to the square root of the frequency due to "skin effect" as Roy mentioned in describing how current penetrates the conductor less completelty due to inductance deeper in the wire. So, loss is greater at higher frequency due to reduced effective cross-section in the wire. Conversely, the loss with a given wire size gets lower as you go down in frequency.

As far as I know, there has never been any dispute over which
direction the energy goes. The problem has always been with your
overly imaginative explanation for how it gets there.

Getting speed on the straights is the easy part. Finding out that
you've got too much when you arrive at the turn is the primary concern.

Richard, the frequency of photons extends from DC to gamma
rays and beyond. You think because you cannot see them that
they don't exist???? RF waves are certainly made up of photons
that you cannot see. There are many more photons that you
cannot see than photons that you can see. If you are relying
solely upon your flawed human sight for the detection of
all photons, you are severely handicapped.

>Richard, the frequency of photons extends from DC to gamma
>rays and beyond. You think because you cannot see them that
>they don't exist????

Photons I do see, do exist, and are NOT "responsible for producing all
electric and magnetic fields."

Photons I do NOT see, do exist, and are NOT "responsible for producing
all electric and magnetic fields."

And electric and magnetic fields exist quite independently of ANY
photons (invisible or otherwise) which, of course, means that photons
were NEVER "responsible for producing" these "electric and magnetic
fields." Note that ALL is inclusive in its totality and I have thrice
demonstrated that falsity.

Like I said, your naive statements propagate a lot of foolishness and
fall far short of illuminating.

So, time for another simple computation:

What is the temperature of an 80M photon?

Looking forward to your fumble.

Cecil,

Have a safe trip.

I want to hear more about this "temporary benign interference". I have
been doing physics and optics for over 40 years, and that concept is a
new one for me.

I am guessing that the "steel clothesline" to which you refer is
probably actually stranded (7x1?) heavy galvanised soft steel wire.

The galvanising is zinc or zinc/aluminium alloy and its thickness has
bearing on the answer for a specific frequency.

The stranding also has adverse effect on the effective RF resistance,
though not as predictable as the zinc coating.

Though it works, there are a number of mechanisms that increase the
loss, and the extent of some of them are quite difficult to predict or
to measure (for the average amateur).

The additional loss of steel wire is less important in an antenna
design that is loaded with bulk resistance, eg T2FD. A reason why
small guage stainless steel wire commonly used commercially on these
antennas isn't necessarily unsound. But that application should not
imply that small guage stainless steel is just as suited to a half
wave folded dipole.

Antenna wire would be one of the lowest cost elements of a complete
system, which questions the cost effectiveness of savings.

You don't need to know my callsign, all you need to know is that CW makes
for more skilled amateurs and that's why we need to retain the
requirement. CW also works a little as a filter to keep the sick, lame
and Lazy off HF. We need to bring back the CW requirement for Techs so we
can raise the intelligence level of conversations on the repeaters.

You think that's bad? Wait until HF sounds 11 meters and you can't find a
decent contact anywhere. You'll see I was right.

I crawled out of my hole around restructuring time. Then the ARRL and FCC
screwed ham radio. I went back in my hole again. Now the FCC and it
appears with the blessings of the ARRL is planning to toss CW all
together. I come out of my hole to fight for the integrity of ham radio
once again, but when the R&O comes out eliminating CW, I'll crawl back
into my hole again. Leaving you and everyone else the problem of trying to
deal with poor behavior and operating practice on the bands. The result
of dumbing down licensing.

Outcome based education doesn't work, what makes you think outcome based
licensing will?

Mark,

You don't know what ham radio is about. I think if you just sit back and
read the threads, instead of screwing them up with your insane babble, you
might learn something. Of course, that depends on whether or not you
really want to learn something.

SC

Cecil, you've been like that since day one. I knew years ago arguing with
you that you'd never change, I don't know why I still argue. You like CW,
but when anyone has ever made an arguement for keeping the code
requirement you tease them.

Ham radio is dead when the CW requirement goes. Then that last step to
pull the plug on it totally will be to eliminate the written exams.

CAN YOU SAY "CB"?

I've read with interest the discussion on the Lattin antenna. I couldnt help but wonder if this type of contruction could be applied to a 1/4 lambda vertical antenna mamde of metal tubing. I can see some neighborhood assciations accepting this as an artistic flagpole design. Heck my wife may even like one for 80,40 and 20 in her flower bed. Our 35ft flagpole has gotten lost among the oaks, we really need something more statuesque.

Jimmie.

All the wire antennas I've built for the last 20 years or so have
been made out of electrical wire from the local home improvement
store.

They alway seem to outlive my interest in them.

Just standard household electrical wiring? So purchase some two wire
(actually three wire if you include the ground wire) electrical cable
and use the black and white wires? Will the insulation withstand the
out doors? Or do you strip off the insulation and use them bare?

Not trying to be funny: "Yeah, he's the one who isn't on the air."

I have the problem and I'll never be a code op.

Samples in typing: "Th enext time; a liitle while". Int he first case
(look, there's a real one I didn't plan)

Starting over: In the first case, I swapped the space and the letter "e."
In the second one I double-lettered the "i" instaed of the "t." (Another
real one with "instead" in the last sentence.)

The problem is real and it's maddening. When somebody tells me I can learn
code if I really apply myself, I am tempted to go back at him with something
like, "True, and you could grow back the hair on your bald head if you
really apply yourself." Yes, it really is like that, except that there's no
combover for dyslexia.

I have to dial the phone very carefully and I must read back phone numbers,
as I do not translate them well among seeing, hearing, writing and dialing
them.

This seems to be a problem associated with the orderly sequencing of things.
Otherwise, I'm pretty good at math and very good at anything graphical
(maps, diagrams, schematics) or verbal (vocabulary, word games, puzzles,
puns). Go figure.

Thanks for asking.

wrote:

I have to think about your response a bit and attempt to understand
some things a bit better. My technical knowledge is limited but I'm
learning lots.

What I have in mind, before winter sets in, is to setup a horizontal
loop just underneath the eaves of the house. Some eyes along the long
wide of the house and stretched along the narrow width. And use a
SGC Smartuner as per
http://www.sgcworld.com/SmartunerProductPage.html.

This will at least get me going on the HF side of things. Nothing
fancy and with not a lot of range but enough to give me a taste of HF
while I think about what I want to do with the trees in the lot and
such.

So one thing I would want to do is to ensure the wire is insulated
from the eyes so there is no sparking or static. And clothesline is
meant for the out of doors which is why I was thinking of it.

Hey guys, do any of you know how to build a cepstrum reflectometer? If so please reply as soon as possible and as simple as possible. IF you don't kn0w how to build it, and you know how to build a time domain reflectometer? Feel free to reply...

Waiting your response...

Standard, single strand, solid, electrical wire, normally with the
insulation left on.

I usually buy blue so it blends with the sky.

Leaving the insulation on shortens the wire required ever so slightly.

The insulation lasts for years on everything I've ever put up.

Not any of the multi-conductor household electrical wire ("Romex"),
find a spool of insulated #14 single-conductor "household wire" at any
decent neighborhood hardware store. Here in the southern provinces it's
called "#14 THHN" which comes in both solid and stranded types and in a
multitude of colors. I prefer stranded wire because it's less prone to
bending fatigue failure than is solid wire. Theoretically

If push comes to shove dial up a local electrician and ask where he
gets the stuff.

Personally I wouldn't string the wire thru bare screw eyes, I'd use the
Radio Shack catalog number 15-853 screwin insulated "TV cable
standoffs" to support it.

> Or do you strip off the insulation and use them bare?

Leave the insulation alone, might get ugly after awhile but it lasts
forever out in the elements and has no discernable effect on the
performance of the wire as an HF loop antenna material.

Brings up a question in my mind which is related to the points you've made about conductivity vs. skin depth. As it then relates to bare vs. insulated copper wire for HF work.
Bare copper wire out in the WX will oxidize which adds a layer of copper oxide on the O.D. of the wire over time. What is the effect of this layer on skin resistance losses at HF frequencies in practical terms? Somewhere along the line I picked up the notion that copper oxide is a pretty lousy conductor and the problem can be resolved by using insulated wire for wire antennas . . comments??

Hi Jimmie,

It will certainly qualify as statuesque, but that would be its sole
quality. You would stand better staying with the flagpole.

Condolences,

Hi Brian,

Consider, insulation is pretty lousy conductor too. Current is going to conduct where it will, and ignore both insulation and oxide. Put a high resistance path in parallel with a very low resistance path (of identically the same length), which one will current choose? The problem of oxide is when it encounters a poor joint and creates a semiconductor.

I am sure that you could, assuming that the concept works in the first
place.
The patent, that you can get online by the way, shows a vertical against
ground set-up.

There are other designs of aerials that use stubs in a similar way, such as
the 'Copper Cactus'.

Why not look at the shortened vertical Dipole. Theres some construction details in the 2006 Handbook.

Another good antenna is the Skeleton slot. Fed with open wire feedline makes a good multi band low angle radiator.

Placing any vertical antenna high as the cb'ers do is just a waste of good RF energy. You split the main lobes and get a lot of high stuff. Which may be good for local stuff.

4 radials closes to earth might work if you have good earth conductivity. Otherwise you will be losing a lot of your power heating the earth.

A vertical on the ground needs 60 radials to be competitive with a good dipole at 40 and above feet.

A vertical fed with high power works because its take off angle is close to ideal as a general purpose DX antenna. I can thrash guys on 20

meters running low beams with a good vertical! Some just dont understand how circuit gain is affected by takeoff angle. Its the difference between the positive and negative gain on both ends this can amount to 10 to 20 db at low angles. Something guys with stacked yagis know of very well.

If you soil conductivity around you is poor there no advantage to using a longer vertical. Your take off angle is determined by the brewster angle. The longer you make a vertical the better the ground system you must have and further out it must be to prvent losses. In restricted neighbourhoods its a waste of time!

Just operating in a urban environment with a vertical your signal will be down 6 db over that same vertical in a open area. Urban areas have a built in loss factor, this has been documented by the ITU. I sit on the edge of urban sprawl and can kill stations with low yagis with a good ground mounted vertical just because i am in the clear.

But suck it and see, try it. It does not cost much. Vertical antennas are not inherently noisy in a quite location. Its just when you use a vertical antenna in urban areas most of the major is intersecting and passing directly through the noise source, so it seems noisier. Try a vertical antenna in the country and compare it to a dipole they have about the same signal to noise ratio.

My 2 Bits worth

Throw the terlin away and you will gain 6db by using a decent mobile
antenna, no joke. The thing is dummy load for dx.

You would not say that about vertical mobile antennas if you screwed a
1/4 wave whip on your vehicle using the same ground

Considering that people claim terlins to work when they tuner them to a
1:1 vswr is laughable really, with something like 40 ohms ground loss

resistance!

You could try a inverted L with a autotuner at the base if you wanted better efficiency. A 6 meter fishing pole with 6 meters of wire horizontal is a cracker antenna.

Worst mobile antennas are those base loaded auto tuning antennas from codan and barret, they have a honest 12 db loss compared to a good monoband 20 meter centre loaded whip.

When you antenna is short you better off using multiple very small radials than a few long ones.

Just forget all the nonses and make a good centre fed doublet with open wire feedline and use it on all bands. No Better or cheaper antenna around.

Yeah and forget those joke Dummy Load Antennas sold by Barret Codan and Bushcomm. They a heap of crap.

I didnt think it was either. We belonged to a club back then that stressed playing by the rules. As a result of this there were a lot of people playing with antennas.

I did witness an intersting phenomenom with this antenna. The beam of the antenna was nearly perpendicular to I-75 and sometimes we could hear truckers as they passed though the main lobe. Over a period of time we were able to deduce that the area of reception was only about a mile wide at this point.

Fred

The theory questions even the extra exam is not that difficult. A
decent electronics tech with an AA degree can master that test. In
fact the tests are so dummied down that just about anyone that has the
ability read and comprehend can pass them with the minimal of
coaching. So if you think so highly your "Theory" tests then I hate to
burst your bubble.

Why should proficiency in one means of communication hender operation
in another? I tend to think that those that are very proficient with
morse code tend to spend more of their time with that mode of
communication. Why should there be a limitation on other modes that do
not wish to use that mode? Most hams learn morse code and then forget
it. I have no issue with showing proficiency in a means of
communication to get priviledges. I have no issues with showing a
proficiency with "theory" as a means of priviledges.

The thing here is usage of the airwaves is a priviledge and not a
right. So what ever the government cares to do in this avenue is fine
with me. I will take advantage of what ever they offer me.

I have apologized to the NG. I also have stated what it will take to
stop such behavoir so go talk to Robeson he was accusing Todd of both right
I returned to ng he ha accused in
my absense Hans of both pedo- and Zoo- phlia. he accused BB of child
molesting

I will not allow Robeson or anyone else to sence by harrassment if
that means firing back so be it

I am sorry that I have found it needfull to use such tactics I
apologize again to the NG in generalmore like 50 perscent the rest would go
with your buddy K4yz
but yes their is still magaic I play with it (although yes acess to HF
would be a help as I learn the ins and out of EME and other VHF+ modes
pity that progress in the ARS is opposed at every turn by hams
themslves with the punce gotcha he wonders why I simple don't bother to ty
impoving my spelling do u hav anyting cognet two say?

478. Homebrew SteppIR Moxon

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-07 15:05:39 UTC
From: jawod <jawod@fuse.net>
Message-ID: <3fff8$4527c2b4$4831cd39$11802@FUSE.NET>
Source record: 51452

I came up with an idea that, to me at least, seemed interesting.
Imagine a Moxon design, a sort of "double D" "[]" arrangement. Imagine this arrangement encased in a PVC square or rectangle.
Now, picture standard copperwire making up the elements and attached to each distal end is fishing line leading across the [] to the other side. This is true for both elements.
Now, imagine a take up spool and motor such that the length of each element can be adjusted in SteppIR-like fashion. With the proper electronics, it seems you have a Moxon with adjustable resonance...a sort of homebrew SteppIR. I would imagine that the useable bandwidth would not be as great and at the appropriate length, the Moxon becomes a two element Yagi.

Any comments? From the "big guns"? "Duff-Man"? Anyone?

Thanks!

John
AB8O

Source record: 51453

The whole benefit in Moxon is the precise dimensions of gaps and bends for optimum and great F/B performance. By opening the gaps you will defeat the benefit and have just sorta loaded Yagi.

The most critical elements of the Moxon are the tail lengths and gap
spacing- change that and you lose the F/B and the natural 50 Ohm feed.

and in stating that you just used the Consitution of the USA as toilet
paper

it is just that simple

the govt officail to regulate radio would derive from the "Nessary and
proper clause" the ITU treaty under the supremacy clause and the rest
to US (or the staes how are then exclude from radio regulation by the
ITU treay)
in partical the Govt has one other source of power over radio a(and
anything else they should not have) the willing of citizens to lie and
take it

The Govt had the power (and legal duty) to do code testing till 2003
when the treaty changed

the FCC has conceeded its intent we are waiting on them to push the
paper

484. Re: Why is copper better than steel for wire antenna?

The local price at Home Improvement stores is less than $25 for 500 feet of 14 gauge wire. I use electric fence insulators from the farm supply store.

I have been disapointed in the mechanical strength of the Aluminum electric fence wire.

We don't have a Radio Shack store within a hundred miles. But I get the idea. I'll go looking for some such.

I guess you got the pablum stains on the pages while sliding your finger along the print, eh? That's probably why you need words of less than one syllable. I heard from our mutual friend Mac N8TT that you're a doctor. A D.O. probably? (Why else with that call sign?) Then of course you graduated from words of less than one syllable to writing less than decipherable prescriptions. Right?

Oh, I believe you when you say the end of an antenna bites. I've often drawn 4-inch arcs with a pencil from the end of a 20-m dipole with 500 w input. The only problem I have with your arcs is that when you stretch a normal-length feedline out to a hundred yards, the diameter of the conductor becomes so small that it takes a megger to measure its resistance. How are you gonna get enough current through it to see a spark at the end of the dipole?

>I did not see an email from you in the inbox... Nope not spoofing my

The address I used was k8do@mailblocks.com. It came back undeliverable--with that address it figgers.

My main reason for answering your posts is to say that my signal gets out pretty well on this band--R9 sig in Australia, yet no skip over Hemlock from nearby Mt. Pleasant. You and Mac are the only Michigan contacts I've made on this band. Pretty neat propagation, eh? Did you know the airline distance between us is only 26 miles?

I'm originally from Mt. P, but left in 1940, then back in 1946 after WW2. Retired to Florida, but became a snowbird when I remet and married my high-school sweetheart in 1996. She is an emeriti professor at CMU, so we live in her house in Mt. P. in summer, and in mine in DeLand, FL during the winter. We're leaving for FL Oct 30, so we won't have time to meet before then, but we

should next summer.

Walt

Hi Denny,

What a wonderful Mother you had! And you're right abou the whiners.

My Dad built radios in the 1920s while I watched begining at age 3. Got my license W8KHK at 14 in 1933, but my Dad didn't regain his interest until 1945, when he became W8YNG. He was net control of the Michigan Emergency Net from 1953 to 1957, prior to his death in 2958. My three sons and I converged in Dayton this year. You can see a pic of us in front of the Hara Arena on my web page at www.w2du.com, Click on 'About the Author' and scroll down to the bottom of the page. There you'll see Bill, W2WM, Rick, W8KHK (my original call), and John, K4JRM.

As I said earlier, we'll have to arrange to meet next summer, that is, if the gas prices are reasonable. Do you get to FL in the winter? If you do, let us know ahead of time so you can stop in. DeLand is just 18 miles west of Daytona Beach, and 35 miles north of Orlando, on Interstate 4.

Nice to meet ya, Denny,

Walt

James,

Rethink what I wrote. I'm not claiming the tests are "all that"..... You are right, they ARE dummied down and NO, you do NOT need an AA degree to pass the Extra. Just some diligent studying. I was merely saying NEITHER test will eliminate the crap - for starters. BUT those who "are" whining about the code - if they get their wish, will then want the written exam dropped too. In other words - FREE - uninhibited passage. IF we gave Drs', Lawyers, Drivers, Pilots and other licenses away like some want the Ham licenses handed out, where would we be? Ham radio may not be all that, but it is what it is. Anything more stripped away from it - and it won't be worth having.

"I" had to learn the code, it really is no big deal. Do I use it? Not much, but I'm still glad I learned it. It was a matter of self discipline. Hey, drop the code......Who am "I" to force it down anyone's throat? That isn't my aim or argument. Again - you're going to see the push for the rest to be dropped too - some just aren't satisfied. Mark my words.

Fred G.

Joergen, I was working along the same lines for a 60M/5MHz antenna
several years ago. I asked the coded Extras on RRAP for suggestions
and got some pretty nasty replies. I hope that you are able to find
the help that you need.

Best of Luck!

duely marked but exactly who do you think is going to push for this?

personaly I will push to cponsolate down the number of classes which
will reduce the number of tests of course and since there will not be
as amny defferent set of band edges the number of question wiull
certainly drop further

but the only people claiming the written test will are those insistign
the code test should should not die

Hey Cecil, you have a good answer.

If a coil is used, how many turns and what diameter?

I read your post and understood it. My beleifs is that those that will
complain about a "theory" test are those that want the license handed
to them. They don't want any kind of test. Unless the government does
that, I still hold that some form of written test is applicable.

I learned enough code and then I never touched a key again. Made two
contacts total via morse code. Never cared for it and never intend to
use it. At the time my interests were more in VHF/UHF anyways. HF was
to much like CB. He who had the biggest amp and antenna was heard.
VHF/UHF systems require more than a big amp and a big antenna.

I whined about the code requirements and still do. But I also
understand, that what ever the government determines as the standard
for obtain levels oflicensing are the rules that I ahve to play with.
As I stated I have no issues with levels of "theory". That part to me
is easier to learn.

Is DSB with carrier still used on the ham bands?. I recently dug an old transmitter I made back in 1970. The plans at the time was set up a low power AM FCC licensed radio station operating in the broadcast band. We had no idea what we were doing except we got the transmitter built. For grins and giggles I fired the thing up and it works just fine. Is anything still happening on 160m AM. I lose track of whats going on because I am in and out of radio these days. over the last few years mostly out

You raise some good points Jim. That's why I've always proposed the following licensing changes:

1: No more automatic renewals. Individuals must retest and pass all elements required for their license class.

2: The passing score for written exams needs to be raised to 85%.

3: Code elements should be 13 wpm for General, and 20 wpm for Extra.

4: Make the no-code license one year non-renewable.

<johnferrell@sprintmail.com> wrote:

>I have been disapointed in the mechanical strength of the Aluminum
>electric fence wire.

Aluminium is not very good material for fence wire and not usually a substitute for steel in general fencing as it lacks the strength of steel.

There are fence wires made from a steel core (typically high tensile) and an aluminium (or aluminium / ~5% zinc) coating, sometimes with a polymer coating over the top. These products are appearing as the new "longlife galvanised" fence wires. Commonly the aluminium thickness is around 30 microns, way less than skin depth at low HF, so they can be expected to perform about as well as the high tensile steel core.

There are other products with a 200 micron cladding of 60% conductivity aluminium over a high tensile core, and they look a good prospect for antenna wire, 80% RF conductivity and 10000% strength compared to the same diameter HDC. For example Gallagher XL 2.7mm diameter wire (200 micron aluminium cladding) should have the same loss as 2.3mm dia HDC, but over 10 times the Gross Breaking Strength.

To determine their likely loss as antenna wires, you need to know the coating thickness.

Owen

That's not dyslexia - it's your fingers and your brain not working
together. "The exnt itme" looking right to you would be dyslexia.

>The problem is real and it's maddening. When somebody tells me I can learn
>code if I really apply myself, I am tempted to go back at him with something
>like, "True, and you could grow back the hair on your bald head if you

>combover for dyslexia.

Except that I type like that too sometimes (and I'm not dyslexic),
which is why, even with a spell checker I reread my posts before
posting them. And I can still copy CW at somewhere between 15 and 20,
although I haven't sat down to copy any long transmissions in over 20
years - but I used to rag chew at 40+.

There's a difference between a keyboard and a key or bug. (Never
could get the hang of paddles.)

>This seems to be a problem associated with the orderly sequencing of things.
>Otherwise, I'm pretty good at math and very good at anything graphical
>(maps, diagrams, schematics) or verbal (vocabulary, word games, puzzles,
>puns). Go figure.

Since CW is more a verbal skill than a written skill, dyslexia
shouldn't affect it much (although I don't know of any studies done on
the subject - it's just a seat-of-the-pants guess).

Why retest knowledge? Not necessary unless your intention is to reduce the ranks of the amatuer radio service. Few if any government priviledges require constant retesting for renewal. Your thinking is not logical.Besides it increases the government and costs. The government would then be forced to charge for licensing.

>+++2: The passing score for written exams needs to be raised to 85%.
>+++
****

Again 70% is sufficient. Raising to the limit you suggest is more a weed out than anything else.

>+++3: Code elements should be 13 wpm for General, and 20 wpm for Extra.
>+++
****

The ITU no longer requires CW for any of its commercial services. Why do you stillinsist on such high levels. Again your motive appears to be more selective as to who may be granted a license.

>+++4: Make the no-code license one year non-renewable.

Why? when this class already has very strong restrictive priviledges. This would not be the incentive to upgrade to a higher license. Some maybe satisfied with the priviledges of this class and making it a one year nonrenewable will not be the incentice to an upgrade path. Instead it will be another step in restricting any growth in the amature radiio service. Then again if you prefer dwindling numbers, go ahead. Radio and its associated costs can not compete with the internet. If I want to talk to some one in Australia it is now far easier to use IRC or other messaging programs in conjuction with the internet. If you intend to further restrict the amature service to nothing more than a "good ole boys club", then you yourself have become the problem.

508. MFJ-259B failure - Diodes?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-07 23:27:01 UTC
From: "n3ox.dan@gmail.com" <n3ox.dan@gmail.com>
Message-ID: <1160263620.855731.40350@e3g2000cwe.googlegroups.com>
Source record: 51382

My MFJ-259B has decided that a 100pF capacitor is a 600 ohm resistive load at 2MHz, and really seems to be having problems with capacitative reactances. Inductive reactances and pure resistances are a little better, but something is distinctly wrong. Pure capacitances are showing up with large resistive components across much of the frequency range of the unit.

W8JI's calibration site suggests detector diode failure as a common cause for sudden problems, but I wonder if anyone else has had this happen? Is it likely the diodes?

Also, if I do need to replace diodes, where can I get some HSMS 2829 Schottky Detector diodes (I think these are the ones?) without having to order 100 of them from Newark? I've looked through Digikey, Allied, Newark, Mouser, Jameco... doesn't look good.

This thing is long out of warranty, it seems like MFJ service times are in the month+ range at least, and i've got access to a temp controlled soldering station and I'm not scared to swap surface mount stuff. Then again, if I can't get the diodes or can't get them in less than a month, I should probably just send it back to MFJ and pay their repair fee; they've at least got the diodes.

Any comments or suggestions on what I should do? I'd rather not be without it for an extended period.

Dan

Farnels has these diodes, they a off the shelf item.

Yeah those little detector diodes are impressive however they very
sensitive. I am surprised nobody has modified there analyzer with 1n23
1n119 top hat packaged diodes. The only advantage of the diodes used is
that the package is cheap! No surprises for MFJ. Macom has the biggest
selection of ceramic packaged detector diodes. They can withstand
static and overload pulses from electronic warfare emitters. Most
electronic warfare receivers which are homodyne or zero if use a
parallel pair of diodes to protect the detector diode. These diodes
typically operate -55 dbm Tss. i dont know if the MFJ uses a forward
bias of a few microamps to increase sensitivity. They also make zero
bias detector diodes which are just as sensitive as biased diodes. macom
have an excelllent range

I would think any detector diode would work, Macom have an exact replacement for the HP unit with much better specs. Only problems is getting parts from them. Since Tyco has just about bought up the whole electronic industry everything is special order with lead times of 6 months.

Super High Frequency Parts company, if his still around may be able to get them for you. He carries all the microwave parts for hams.

yes, look somewhere around 1880-1890 or so for some AM activity on 160m.

Dan,

My MFJ-259B had a diode failure due to static and had to be returned for repair. There is a simple test that you can do. It is based on the W8JI alignment procedure but does not require that you open the unit. Here is the procedure:

1. Get the MFJ into test mode using the procedure described by W8JI (http://www.w8ji.com/mfj-259b_calibration.htm)

2. Use the mode button to step to the R-S-Z display. Set frequency to 10 mHz. With nothing attached to the SO-239 you should see R around 230 to 250, S close to 0, and Z=255 or a bit less. S and Z need to sum up to less than 255 no matter what resistance is across the input. You will be off a little bit if alignment is required but you will be way off if one of the diodes is shot.

3. Short the SO-239. R should stay the same but S=255 and Z=0. Note S & Z sum up to 255. If your diodes are shot you will be way off as mentioned above.

If you go to the trouble of replacing the diodes you might want to put in a matched set of 50 ohm resistors in the bridge (R21,R22 & R24) in order to get better alignment. Check the diodes for a match in characteristics as well.

You have the wrong part number for the diodes. They are HSMS-2820 and are in stock at avnet, newark and arrow (http://www.arrownac.com) as part hsms-2820-BLKG for 34 cents each - no minimum. You might be able to talk Avantgo into sending you some as samples. You could always try registering on their website for samples or you could call and speak to one of their application engineers.

Hope this helps. Good luck - Roger

From: "n3ox.dan@gmail.com" <n3ox.dan@gmail.com>
Message-ID: <1160273572.399173.216300@k70g2000cwa.googlegroups.com>
Source record: 51389

At 10MHz, I get the following:

Open: R 255 S 003 Z 248

Shorted: R 232 S 255 Z 001

Decent 50 ohm termination: R 001 S 127/128 Z 121

At 3 MHz my 100pF +/- 10% capacitor reads164-j530 ohms on the Impedance display ... it seems to get X right... Furthermore, setting the meter to capacitance makes it read about 108pF... but there's this big resistive component.

In the test menu, this cap reads R 255 S 023 Z 247 at 3 MHz

So maybe I just need an alignment... I suppose it wouldn't hurt to try it if I can scare up some precision terminations.

I wouldn't consider these numbers "way off" ... this reading of resistance at low frequencies had got me worried that something was way wrong, but will an alignment fix this? I guess I can check through the W8JI alignment procedure with the proper loads before I start twiddling things.

Dan

Source record: 51390

Dan,

I repeated your test with the 50 ohm load at 10 mHz and got R 006 S 127 Z 126 which is pretty close.

With a 75 ohm termination reading is R50 S102 Z152
With a 200 ohm termination reading is R147 S50 Z204

With a 100 pf cap at 10 mHz I read R = 0 X=145 109 pf and R245 S083 Z242

With a 100 pf cap at 3 mHz I read R = 0 X=554 95 pf and R246 S023 Z255

Here are some things to check:

1. Try 75 and 200 resistors and see if you get readings close to mine. If you do your diodes are probably OK but you need an alignment.

2. Use the 100 pf cap and starting from 3 Mhz start increasing the frequency. Does it read R=0 some of the time - most of the time?? Try another type/size of cap.

3. Attach about 20 feet of coax to the unit and put a 75 ohm resistor at the other end. Your SWR should be about 1.4 to 1.5 depending on coax type/length. Start at 2 mHz. and start increasing the frequency to 30 mHz. The SWR should gradually get lower as you increase frequency due to cable loss. However it will go up and down a bit (+/- .1) at certain frequencies due to alignment and instrument error. R & X should change in a smooth fashion as you change frequency (the cable is an impedance transformer)

If you attempt alignment here are some tips.

1. Follow the procedure at W8JIs site - not MFJ. Tom was the designer and his site has the latest info.

2. Use precision resistors placed deep into the connectors and short leads for minimum inductance. I used metal film 1% and picked the best ones with an accurate ohm meter.

3. Use a stable power supply to power the unit. If you try to use batteries alone you will find the voltage dropping with time and you will not get consistent results.

4. Be prepared to repeat the process several times in order to get the best results.

5. It will never be perfect. The 259-b is an 8 bit implementation,
the bridge has inherent inbalance due to resistor/diode characteristics
and the log buffer does not match the diode characteristics perfectly.
This isn't a VNA but it is a useful low-cost instrument.

Hope you keep us updated. I am interested in your results.
Roger

Fuck the code only shit. Why should that be the only element? Why not make all amateurs retest in ALL modes, at all frequencies, et al. And what the hell, while we're at it, let's just go ahead and make it yearly. Don't let the old geezers off so easily. When a new mode is adopted, or allowed, make those bastards show proficiency there as well. That should just about do the ARS in. Why should you have it your way, SC?

Well said. SC and his ilk are what is wrong with the ARS today. But hell, who knows when I will need morse to facilitate my rescue from a capsized cruise ship in the Gulf of Mexico. I will be the one! No one will know there are really people inside the ship, unless of course, I pound the hammer I had with me on the inside of the hull. And to boot, the Coast Guard no longer teaches morse, so hopefully SC will be there to copy.

BWAAAAAAAAAAAAHAHAHAHAHAHAHAHA!!!

I don't hear/perceive/recognize/distinguish/discriminate the dits and dahs
correctly. I can learn that dit-dah-dah-dit is G (or whatever it is -- I am
not sure and I am certainly far, far beyond caring) and five seconds later
not be able to distinguish it from dah-dit-dit-dah.

What's the fix for it?

200 (197 on my DVM) ohm termination:

R 155 S 051 Z 197

75 (74.5 on my DVM) ohm termination

R 047 S102 Z 146

With the cap sweep, with two different caps (a 100pF doorknob and a 30pF air variable trimmer), R is almost never zero until I get up into the 60MHz+ range and even then, rarely.

With the coax check, the SWR oscillation amplitude is about 0.2 or so; 1.1-1.3. R and X vary smoothly and more or less cyclically.. I guess the oscillatory SWR variation with frequency is incorrect... I do get more than you mentioned and more than one might expect... i've got about 40 feet of RG-55U terminated in the 74.5 ohm termination that I used above.

- - - - - -

>From what you've said, it seems like alignment time. I guess the large resistive component on capacitors at low frequency is a numerical artifact of a slight misalignment... because the R S Z menu values are really fairly close to yours. I'll build or find some precise SMT terminations and go at it. Thanks much for your help and I'll post after I do the alignment.

73,
Dan

For what it's worth - I can fully quiet a repeater roughly 18 miles from my home, having radiant heat barrier, with my 2 M HT at 5 watts but not 2 W - a local repeater around 7 miles away with 1.5 W but not 1/2 watt. Kenwood TH-K2AT with Diamond SRH77CA antenna (18") in place of the rubber ducky. Oh yes, those are with the aluminum storm panels in place on the windows too.

I guess it won't hurt us to try it with HF will it?

Thanks for asking the question, I've been meaning to.

Jim Kelley wrote:> As far as I know, there has never been any dispute over which
> direction the energy goes. The problem has always been with your
> overly imaginative explanation for how it gets there.

I'm just quoting "Optics", by Hecht for how it gets there. Hecht's irradiance equation tells the whole story. Total Irradiance = I1 + I2 + 2*SQRT(I1*I2)cos(A) where A is the angle between the I1 and I2 electric fields. The last term is the interference term. If it is positive, the interference is constructive. If it is negative, the interference is destructive. If it is zero, the signals are orthogonal to each other and no exchange of energy takes place. Please note that the dimensions of Irradiance and the dimensions of average power flow vectors (Poynting vectors) are the same. Hecht says that in the localized absence of a source, any constructive interference must be equaled by the same magnitude of destructive interference. The destructive interference that eliminates reflections on the source side of the thin-film coating on non-reflective glass is exactly offset by an equal magnitude of constructive interference on the other side of that thin film surface. It's all there in "Optics" by Hecht.

530. Joining galvanised wire mesh (chicken wire) ground plane

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-08 17:13:55 UTC
From: ferrymanr <richardferryman@btinternet.com>
Message-ID: <iZadnf9CAvFLrLTYRVny2Q@bt.com>
Source record: 51404

To improve the ground plane of my roof mounted HF verrtical I plan on lining the flat roof of my house with chicken wire (wire mesh) which comes in rolls 6' (2M) wide. As this is fabricated from fairly thin galvanised steel wire I am not sure how to join the strips of mesh or make ground connection to it. Can it be soldered?
I also plan on retaining the radials which run from the base of the antenna to the edges of the roof and down to ground level. Should these be above or below the mesh?
Thanks de Dick G4BBH

You're not supposed to learn dits and dahs, any more than, in French
class, you learn the letters of the alphabet. You're supposed to
learn the words in CW. Anyone listening to the dits and dahs
(dyslexic or not) will never gain any proficiency in CW.

>What's the fix for it?

Learn it by the sound, not by the individual element - the same way
you'd learn any other language. See if a ham club near you has
classes. If they do, see if the person teaching CW knows the
difference between learning the dits and dahs and learning CW by
sound. If s/he does, take the course.

I started teaching myself CW (as a kid) by individual letters. After
using it on the air for a year (we had very little choice in those
days - Gonsets were too expensive for most of us, and there weren't
too many other ways to get on 2 meters) I was listening to the
content, not the dits and dahs. I still have to "hear" the sound in
my head when someone posts dots and dashes in a Usenet post - I never
learned to "read" "written CW".

>>well ADA says you and I should be allowed to take an acodated test with
>>US choosing whatever accomodation we choose

No it doesn't. There's something in there about the test actually
testing for the thing it tests for.

Can you just imagine a totally blind from birth person "choosing", as
a test for a job that requires color matching, a test to see if he can
tell the difference between Braille labels on paintings? Or a "test"
for someone who can't drive due to a disability consisting of testing
his ability to hail a cab? A test for the ability to receive AND
DECODE CW consists of your listening to, or seeing, *CW*! We don't
test a translator's ability to translate French to English by giving
him the English translation and seeing if he can "read" it.

That makes as much sense as a man insisting that it's sex
discrimination to not hire him to model women's clothing - something
that's been thrown out of the courts so many times it has permanent
skid marks. Sue the FCC if you like, but make sure the courtroom
doors are open or you'll get hurt when they throw your case out so
fast the splinters will fly.

>> persnaly Id choose a code
>>reader and would of course oviate the test all together. fairer still
>>is stop dumbing down everyone in the service with test

Fairer still is to accept that there are a number of ways to get on
the air, one of them being to prove a certain very low level of CW
proficiency. (5 wpm isn't even reading CW, it's "decoding" individual
dots and dashes.) Would you accept a blind person's insistence that
he be allowed to travel the same way that you do - by driving his own
car? After all, he's disabled, so he can choose whatever test he
likes to get his driver's license. How about a test listening to
someone talk and seeing if he can hear the speech?

>> that greatest
>>physists of the last century could not pass if they wanted to ham I
>>refer to Einstain Hawkings and Dirac

What has being a physicist to do with being a ham? But I'll go along with that - in order for you to keep your license you can skip the CW portion of the test, as long as you produce a PhD in physics. Deal? (BTW, Einstein, Dirac and Hawking weren't/aren't physicists. They were/are all mathematicians, although that's questionable in Einstein's case.)

Hello Dick,

Whether you can solder the chicken mesh depends on the amount of oxides. When it is very glossy (like a fresh soldered PCB), you may use solder with a flux core (as you use for normal electronic assembly or rework). I do not like this method for large solder jobs.

However, when it looks dull, you should use the aggressive paste or liquid flux in combination with solder without flux (as used by plumbers). The liquid flux (I think zinc solution in hydrochloric acid) works well (I'm still using it) However, after soldering, you have to clean thoroughly with abundant warm water with soap to avoid corrosion. The aggressive flux stays active, also at normal temperature.

I prefer the aggressive flux in combination with cleaning. After cleaning, you can use normal flux core solder.

When I solder several pieces of mesh together, I first strap them together with metal wire (in their final position), so I can fully concentrate myself on the soldering.

I do not know your radial arrangement, but when the mesh will replace the radials, I would remove them.

When the existing radial wires are not insulated, you may get unreliable contact between the mesh and the radials. In combination with small mechanical movements (wind), this may generate noise.

As the conductivity of wire mesh is not that good and somewhat unpredictable, you may put (solder) small radial (about 30cm) wires from the point where you ground your coaxial feeder.

I hope this will help you.

> (BTW, Einstein, Dirac and Hawking weren't/aren't physicists.
> They were/are all mathematicians

Wrong. Here's part of Hawking's bio: "In March 1959 Hawking took the scholarship examinations with the aim of studying natural sciences at Oxford. He was awarded a scholarship, despite feeling that he had performed badly, and at University College he specialised in physics in his natural sciences degree. He only just made a First Class degree in 1962 and in [1] he explains how the attitude of the time worked against him:

"The prevailing attitude at Oxford at that time was very anti-work. You were supposed to be brilliant without effort, or accept your limitations and get a fourth-class degree. To work hard to get a better class of degree was regarded as the mark of a grey man - the worst epithet in the Oxford vocabulary.

"From Oxford, Hawking moved to Cambridge to take up research in general relativity and cosmology, a difficult area for someone with only a little mathematical background."
(From http://www.gap-system.org/~history/Biographies/Hawking.html)

From http://archive.ncsa.uiuc.edu/Cyberia/NumRel/EinsteinLegacy.html:
"Einstein's college record as an unenthusiastic student is fairly well known. So, too, his independence and questioning of authority, all of which may have prevented him from landing an entry-level academic position once he graduated in 1900 with a degree in physics."

From http://nobelprize.org:
"In 1909 (Einstein) became Professor Extraordinary at Zurich, in 1911 Professor of Theoretical Physics at Prague, returning to Zurich in the following year to fill a similar post. In 1914 he was appointed Director of the Kaiser Wilhelm Physical Institute and Professor in the University of Berlin."

So both Hawking and Einstein were trained as physicists, and had the equivalent of a minor in mathematics. Only Dirac (originally an electrical engineer) had a major degree in mathematics.

The ball lay dormant on the 1 inch line with 2 days to snap it and....

OK, the quick Xeroxed answer from my own posting, some time earlier:

0ï¿½K or so close as to be indistinguishable;

For extra credit (sic, nothing extra as nothing was credited to Cecil
in the first place):

What is the actual answer to within NOT ï¿½69%,
but to within one order of magnitude!?

All may note the munificence of allowing up to 1000% error allowable
as a "correct" answer. Certainly the master of Xeroxphotonic-zen
might grasp at a straw? After all, how close do you have to be when
you are already dead-nutz on to zero? :-0

[Hint, when I taught Electronics in the Navy, my students swore I
always had an "Ace-Buster" in the quiz.]

Thank you Wim

I have in my household toolbox a good supply of a very agressive flux which I often use as a final attempt to solder to some modern PL259 connectors. I just tin the surface with the aid of agressive flux then clean it all up before soldering normally. I think this and plumbers solder may work. When the roll of ckicken wire is delivered I will try a test run.

As the ground mat will be of a lossy material I am hoping the large number of effective rf paths in parallel will mean that losses will be reduced. My present radial system is four insulated wires that run to drains at four corners of the roof and the down inside the plastic drain pipes to ground level. Approximately 16 metres each. There are a futher four radials which onle go to the edge of the roof but are only about 4 metres long each. I would lose these four short radials but keep the longer ones. The wire mesh mat would be 6M by 7M and would be much better than those short radials. I can solder a few radial wires from the base of the antenna to the mesh. However if I solder each wire to the mesh at, say, 500mm intervals I could end up with more galvanic corrosion particularly as the air is very salty in Dover.

The weather is changing and I think I chose a bad time to start this :-(

I have a Mosley tribander with the following symptoms:

SWR on 20 is 2:1 and there appears to be no pattern or it is very skewed. On the antenna analyzer, it is showing 100 ohm impedence. The other bands are operating normally.

My guess it one of the 20 meter traps in the driven element has either roasted or a wire has come undone. That would make half the antenna too short on 20.

Before I go up and take it down, anyone care to venture what I will find? I would like to be prepared so I can fix it with the least amount of downtime.

Wow! Same here.

Additionally, I had the shop make me a plow hook to help me pull up the
old ground radials as I had a concern for arcing (diode action) between
the new and old ground system. I would pull the plow around with a small
tractor and pull up the old wires.

Once you have a mesh size of about 1 ft square it looks like a solid
copper sheet to RF. Putting your radials underneath will achieve nothing
they will be screened by the mesh.

Its also doubtful if they will have any value with such a high density mesh.

Galvanised wire wont last long laying on the ground. You can buy some
mesh at some places which is actually coated with copper. Its plated
with copper. Bird breeders seem to be demanding this stuff more and
more, which is very convenient to say the least.

You will have to solder mesh. The problem is that after the galvenising
process there is a nasty muck left on the wire thats hard to remove.

I would use a general purpose flux and use a pain brush to apply the
flux and leave it overnight to eat this crud away. I would then solder
the next day using heavy flux. Just watch your soldering tip, i would
wash it regularly because the flux is so aggressive it will eat away
your tip doing such a big job. I would use a very cheap solid tip iron
that you can file away and wash.

To me the job is such an horrendous thought that laying down 60 clean
copper wire radials looks like a simple job!

To each their own.

Greg

Now if by "words" you mean the collection of dits and dahs that make up an individual letter, I totally agree with you. One should never resort to counting dits and dahs. However, IMHO, the next step to recognizing words (ie groups of letters) comes with time and a lot of experience. I would also agree that until one can copy "words" by sound, that there will be a certain speed limit that you will not get past: For me that wall has been around 20 wpm or so, depending on the quality of the sent code.

FWIW, I have a hell of a time copying code a slow character speeds: < 10wpm character speed. At this speed, I no longer hear the 'sound of the letter', only a bunch of dits and dahs. I find myself playing each collection of dits and dahs back in my head at a higher speed --- bizzare. I first learned slow code with farnsworth (21 wpm character speed) and longer inter character spaces to give the effective slower WPM rates. Increasing speed involved reducing the inter character space time.

One could test using light rather than sound if the disability were auditory in nature. Or by feel --- with a vibrating device delivering the dits and dahs.

Part 97.509(k) The administering VEs must accommodate an examinee whose physical disabilities require a special examination procedure. The administering VEs may require a physician's certification indicating the nature of the disability before determining which, if any, special procedures must be used.

If one looks at the Basis and Purpose for the government licensing Amatures, I am not sure I see much justifcation for continuing the CW testing. I am a KNOW CODEer. It took me a LONG time to learn code. It was one of the hardest things I have had to learn. It is still hard for me: Although it is my preferred operating mode. I must like pain. I do see the requirement of learning code to be good for THE HOBBY: It introduces new hams to a fun part of the hobby they might not therwise find out about. Though I am not sure it is the role of the FCC to do what is best for THE HOBBY.

since you seem to be a mode to listen let me try Itis my understanding
and beliefnthat the Mandate legaly of the FCC is to serve the interest
of the PUBLIC in all of it regs (at least that is the thery)

Therfore in my If some one made the case that Code testing was good
for the ARS they have NOT finished the job for making it a requirement
Klien is found of throwing up red herrings (and it is begining to
realy stunk from that

the Facts is CW is not required to achive the stated pruposes of the
ARS

many Hams NEVER use it and many rarely do

the question the ProCoders avoid is how does code testing benifit the
PUBLIC at large?

if there answer it does not realy that it can not be shown to then the
question of wether it benifits Ham radio is moot and with the end of
the treaty requirement I cointend (and others) that constutituionaly
the FCC lacks the POWER to require it

when you add ADA which allows the disabled to choose thier accomdation
(the FCC section you cite is belived by LWAYERS to LEGALY invalid, all
it takes about 5K dollars to spare to prove it

if an ADA chalange went we would have people like efectively not
taking the test and yet demtrating that we HAVE some abilty to use the
mode I have quite a bit of on AIR CW work with computers (I engaged
for 2 reason to see how well it worked and to provide a an interactive
target for code practice to friend of hgoing for various level of
license surely even my worst detractors will grant if I can follow MY
typing translated to Morse Coded CW at a given speed you can pass a
test at the same speed)

as to machine morse in general I find I can decode with machine and
panographic signal display to alow to see the signal I can follow the
going of ARRL straigh key night fairly well, why isn't that enough if
there were a need for CW?

The stated purposes as put forth in Part 97 would seem to support that. In case you didn't notice, I am not saying the FCC should be requireing the CW test.

>
> many Hams NEVER use it and many rarely do

True. And many Hams use it. I was on 20 meters this evening and the CW sub band was wall to wall operators --- much more than on the phone subband --- not that means manything special.

>
> the question the ProCoders avoid is how does code testing benifit the
> PUBLIC at large?

I suspect you are being kind. I fear many want the code requirement so as to protect their vision of what Ham radio should be. I am not sure that requiring CW and not requiring proficiency in any of the digital modes makes any sense. Its the inconsistency that seems weird.

>

I'm not sure I get your point. I can have someone read me a book (books on audio tape) , or I can read it myself. I prefer reading it myself. However, listening to an audio tape doesn't demonstrate that I can read.

>

My CW skills are always a challenge. Yet I can usually copy (<20 wpm or so) better than most software programs .. especially in noisy conditions QRM or QRN.

Again, I am not sure I think CW should be a requirement. I think it is good for the HOBBY. I am not sure it is relevant to the service regulated by the FCC.

> cross-posting to RRAA?

We're rebuilding RRAP. We need to alert internet hams that we are getting general amateur radio and policy threads going again there. Many of the good hams on usenet left RRAP when Mark Morgan, and Roger Wiseman polluted the group, but discussions have started there again. Cross-posting will end in earnest once good hams move back into RRAP, and the riff-raff like KB9RQZ, AB8MQ and N0VFP move out.

Looking forward to more policy and pro-CW discussions with all you fine hams. :)

73, and good luck in the contest.

It's hilarious watching you CB'ers whine about CW. Well don't worry, it
looks like the FCC is going to give you your dumbed down licenses.

Could you pass all the tests again today, or would you have to study a
little first? My arguement has always been for the quality of licensees,
not the quantity of them.

>>+++2: The passing score for written exams needs to be raised to 85%.

Requiring an 85% passing score means more study before taking the exams,
which translate to a better understanding of the material. My arguement
has always been for the quality of licensees, not the quantity of them.

>>+++3: Code elements should be 13 wpm for General, and 20 wpm for Extra.

Hams should be skillfull. Proficency at CW gives hams a way to
communicate, when no other way might be possible.

>>+++4: Make the no-code license one year non-renewable.
>

Requiring future study in order to continue to be licensed will make for more knowledgable hams. They will be assets. A national resource. My arguement has always been for the quality of licensees, not the quantity of them.

> Instead it will be another step in restricting any growth in the
> amature radiio service. Then again if you prefer dwindling numbers,

> nothing more than a "good ole boys club", then you yourself have
> become the problem.

Everyone is welcome in the "good-ole-boy" club if they're not lazy and are willing to learn. If not, there's always CB for them. My arguement has always been for the quality of licensees, not the quantity of them.

Having to work a little to get/gain something gives a little sense of pride in the accomplishment and you appreciate it and take care of it. It's valuable.

Getting handed something for nothing cheapens it. Don't cheapen ham radio. Rigs don't come with kill-filters to notch out bad ops and lids, so let's support policy that minimizes the number of lids on the bands.

BBBBBBRRRRrrringgggggg!

No point in waiting two days for Cecil's fruitless search for
Xeroxable material - even with a latitude of one order of magnitude
slop above and beyond his usual ï¿½69%.

A Photon in the (bottom of the) 80M band would have the equivalent
temperature of:
60ï¿½ï¿½K
for extra credit, the answer would have to have fallen somewhere in
the range:
6ï¿½ï¿½K..600ï¿½ï¿½K

Still pretty darn cold (and a far sight harder to answer than simply
stating near 0ï¿½K which was a sufficient answer in the first round).

This, of course, is simple Black Body radiator mechanics that novices in Optics would have migrated through in High School. Cecil's Photon radiator seems to need serious back-flushing.

Dare I challenge our master of Xeroxphotonimetry as to the temperature of a 10M Photon? It would seem that if you cannot compute the simple matters of heat, you are certainly the person who needs to ask "Where Does the Power Go?" :-0

Awaiting more Photonic (no, I did NOT misspell pathetic) nonsense from Cecil....

If that is a TA33JR, and you are running more than a few hundred W, quite
likely. I blew the 15 m trap on mine. Good thing; the Hygain TH3 I replaced
it with is better in all respects.

But not, as requested, by using an electronic CW reader to test
whether the testee could read the resulting Latin alphabet display.

>If one looks at the Basis and Purpose for the government licensing Amatures,
>I am not sure I see much justifcation for continuing the CW testing.

Or theory - the only valid test is a practical one to demonstrate
knowledge of operation, which has never been given, and the laws. No
one builds any more, so knowledge of the circuits inside a radio isn't
really needed. Nice if you want it, but not needed to operate.

>Though I am not sure it is the role of the FCC to do what is best for THE HOBBY.

If you look at the FCC's entire justification for the hobby, you'll
see that CW wasn't an issue once AM was invented. But knowledge of
digital modes should be tested for now. If the justification for the
hobby has anything to do with anything.

Now try when the signal is a few db UNDER the noise floor and you'll
see why CW is still a valid mode. (I'm sure that, as a CW operator,
you know what I mean.) How many db under the noise does a voice
signal have to be before it becomes just part of the noise? (I
believe the actual figure is 6db ABOVE the noise to be readable - that
gives CW an advantage of about 12db.)

That's about twice the normal wall. You may already be past it
without realizing it.

>FWIW, I have a hell of a time copying code a slow character speeds: < 10wpm
>character speed.

You remind me of when I took the CW test in Navy boot camp. My paper
consisted of Ts and Es. When the instructor challenged me, I told him
that I really couldn't copy anything under about 10, and I was more
comfortable around 30. (I was taught CW by W2RD, who could copy 65
with a pen and an ink well, and talk to you while he copied.) The
instructor took my challenge and cranked the TG34 (or Navy equivalent
- I can't recall any more) up to around 20. When he saw me yawning he
cranked it up to 30.

5 minutes of perfect copy later ...

But 1wpm (which is what they gave you after "teaching" you E, I, S, H,
T, M and O) was impossible for me. I couldn't hear the lengths of the
spaces well enough to tell where the letters ended.

That's the method of Jerry Ziliac, who sends the code at 21 WPM, so that the dits and dahs become a single entity. That only worked for me for some of the characters. The only 4-element Morse I know for sure is <Q> DAH-DAH di-DAH from the mnemonic PAY-DAY to-DAY. All the rest are a jumble.
Sorry -- I failed at this enough times to know it's not hap'nin'.

Really depends on the operating frequency. If you can do NOT scrimp on the coax. I have several runs (over 600ft total)of Davis "Bury Flex" 9914 which has advantages over 213 and 9913 with loss figures very nearly the same as 9913 / LMR 400 hardline. It is very flexible (good for rotator loops)and can be directly buried. It is highly abrasion resistant and wildlife resistant (gnawing,chewing) and is non-contaminating. It accepts regular pl259's as well. Good luck

Hi Dana,

Welcome to the group. To explain the alpha-numeric soup in my reply,
I was trained in Radar Systems before being cross-trained as an
instructor in RF Communication Systems (I then migrated into Precision
RF power measurement out to 12GHz).

The first class I taught was a two week course in the theory and
maintenance for the Collins R-390. I also taught the four week course
for the Collins URC-32 (very few seen in amateur application as
KWT-6). I taught other equipment as well, but they are even more
obscure to Hams. The Collins gear was like learning to drive and
maintain a Rolls-Royce.

>Does the Power Go?" :-0
>

Hi All,

Pushing further down the humiliation trail, if one considers the pain
of lowering temperatures into the microKelvins, one question arises:
How?

Dare I day photons? ;-)

Those same photons to have been claimed to be the source of ALL fields
and the inspiration for electrons are used to "calm" atoms (or corral
them) so that their jitters are reduced along with temperature. Hence
we return to Cecil's inability to express photonic pressure where it
counts most (shuffling those atoms). At the jeopardy of starting more
gibbering, we have photonic tweezers that move atoms around in quantum
dots.

The next esoteric observation comes with the introduction of the
Phonon, which is a sound wave that can move through material faster
than light. That, of course, is highly qualified because phonons
migrate through far more materials than light can. Albeit that rare
distinction, the frequency of that sound commonly pushes past 10s of
Terahertz (or as low as an 80M QSO).

The Phonon (not the Photon) would be that natural progression into
"Where Does the Power Go?" but would be another fumble at the 1 inch
line with a goal-to-goal reversal.

I was an I level DECM tech.
I maintained the ALQ126, countermeasure system, the ALR 45, 50, and 67,
receivers and pulse analyzer, the USM 406, flight line test set, the box
that helped the O level guys sweep the lines and verify the ew equipment,
and the ALM 106 test bench, one of the first automatic test benches made,
and its replacement the USM 458. I was assigned to an A6 squadron, that
swapped out a few years before I got out to FA18's, but I was detailed out
to support them via the IMA shop.

I went into comm, when I got out, worked for a Motorola service shop
maintaing smartnet trunking systems, as well as conventional repeaters and
systems, then went over to Nextel as a cell site tech/performance engineer,
and then over to VoiceStream as a switch tech and performance engineer.

I see that guy has not answered yet about the temp, that thread is kind opf
amusing.

Continue to use the radials on top of the roof... Install the mesh under the roof (attic I assume) and lap it over the rafters and just twist the free ends to each other so that the mesh is relatively one piece... Don't bother with solder.. Don't waste your time connecting the radials to the mesh... The radials will couple with the mesh electromagnetically...

If you are planning on putting the mesh out on the roof (I would not because it will rust and disintegrate in just a few years.) It has to go underneath the radials, not over them... Again, do not mechanically connect the radials to the steel... Just the proximity will couple them... Think twice about putting the mesh outside... You will have a nasty mess very soon...

> appreciated. Thank You.

You can try several thinks. One is a J-Pole antenna, if you have enough room.
It can be made from clear twin lead, like the kind that come with FM stereo
systems.

Another choice would be a dipole. Two 19 inch pieces of wire will do fine.

Using the right thickness of wire and small enough coax would make it almost
impossible to see.

Due to the polarization issue, a horizontal wire is not very usefull

You can also find if you look around a base for a "rubber duckie" type antenna
that has a suction cup. You use it to put mount your antenna on a window
while you are using it.

73,

Geoff.

While not as central to the hobby as it was in the 50's and 60's. There are
a lot of builders out there. Elecraft have thousands of radios out there.
I am sure the Norcal series radios number in the many of thousands.
Personnaly I have e K1, K2, (KX1 on order) and a Norcal 40M in addition to
an ICOM on KF.

> so knowledge of the circuits inside a radio isn't
> really needed. Nice if you want it, but not needed to operate.

Circuit knowledge hasn't been NECESSARY for decades. Most kit radios of the
50's (I build some Heathkits ,myself as a kid and helped my Dad with a few
large projects) had excellent instructions.

.

Thanks Denny but unfortunately the flat roof has no access under. As far as
I can judge the ceilings have about a foot of insulation and beams above
then (probably) timber and is covered in several layers of heavy duty
bitumen based roofing material. The mesh will have to go on top as I think
the XYL would complain if I stapled it to the lounge ceiling.
The chicken wire will have a secondary function of deterring the large
number of seagulls that plague the town (Dover) :-)

Dear Mr. Buck,

Which Mosley do you have? Check 15 meters as well. It could be the
outboard coil on that radiator. 20 meters is not trapped but a
summation of the entire element. Please feel free to call 636-583-8595
for further assistance.

73,

Gary
Mosley Electronics, Inc.

Not necessarily, if he is just operating on 160M and 75M, and maybe
even 40M ... and if his distant antenna location is enhanced over what
he could obtain closer.

Dick, the usual galvanised, chicken wire available in the USA is good for 3 seasons near the ocean, tops... Then they turn into rust balls... Unless your chicken farmers there near the coast have better materials available I would be wary...
The gulls that hang around my boat will stand on anything, I doubt that chicken wire would bother them... I also doubt that putting the mesh on the roof will make a major improvement in signal strength, especially if it is above the radials... First your radials are already elevated above the ground a significant fraction of a wave which reduces ground losses... Putting your money/energy into having 6 or 8 quarter wave radials for each band is more likely to show a better result...

Hi Dale,

I couldn't resist.

If you make the rhombic with stretchable mounting points (and do not
load the end of the rhombic, so as to make it bi-directional) you can
change the major axis. This would alter EW to NS, and, I bet, if you
didn't stretch it strictly to the typical elongated axis (the major
axis) you would probably fill in the lobes in between.

However, this (admittedly rube Goldberg design) and the original
suggestion of a rhombic seems prohibitive in a neighborhood already
far too sensitive to even a quarterwave vertical.

Richard,

In the interest of fairness, Cecil said he would be taking a
motorcycle trip over the long weekend.

At 3 MHz I get 144 micro Kelvin by multiplying frequency by Planck's
constant and dividing by Boltzman's. My daughter had a similar
problem in her High School freshman Earth Science class a few weeks ago.

It might not be entirely fair to translate a lack of response to a
lack of ability. There are other factors as well, among them being
lack of even the slightest amount of interest, and difficulty
deciphering what the heck you are talking about from one moment to the
next. ;-)

They had those well into the 1980's. man I really do miss those.

I have built more than my fair share of kit radios over the last couple of decades (its even more fun trying to build them by braille). its still an excellent learning experience (there is always going to come a time when being able to use a soldering iron will be helpful in repars).

Hi Jim,

Fairness counts, to be sure. Reputation informs us all otherwise. I
am not responsible for Cecil's reputation, so impugning an opponent is
a matter of local custom.

114 micro Kelvin certainly falls within the parameters of the question
offered. I dare say Cecil would have been silent on the specific
matter, irrespective of his recreational activity.

As for the specific difference between you and your daughter's
computation, I use the Wien Displacement Law. It, too, employs the
method you describe (albeit with Boltzmann's constant divided by
Planck's constant instead as it is frequency not wavelength
descriptive), and with an additional constant of multiplication
(2.8214). By this method, your 144 micro Kelvins represents 8.466 MHz
for the peak wavelength.

>There are other factors as well, among them being
>lack of even the slightest amount of interest

The nature of posting to the group satisfies that quite simply: folks
move on or become part of the thread. That has been adequately
demonstrated here.

>and difficulty
>deciphering what the heck you are talking about from one moment to the
>next. ;-)

Barring calls for specific explanation, I always treat such whining
for what it is. Clearly you are neither whining, nor
ignorant/disinterested in the topic. I take it for granted there are
a multitude of others who choose to remain silent, but not uninformed.
Most will take notice I did not open the door of this side-thread, but
having crossed the threshold, I command the topic.

Richard,

To be a bit fussy, the temperature of a photon is not defined. Only a distribution of photon energies can be defined with a temperature (sometimes). Assuming a standard blackbody model, your answer is correct of course.

Perhaps Cecil was trying to recall the formula for the temperature of a single photon. He might be looking for a while.

Hi Gene,

Fussy is the name of the game here in this forum; and fussy will
ultimately dominate; hence I defer to your amplification. I suggested
a black body model late in the game certainly, and only through
allusion to the frequency of the peak wavelength.

>Perhaps Cecil was trying to recall the formula for the temperature of a
>single photon. He might be looking for a while.

Ah! Fussiness has been replaced with abundant generosity. Myself, I
consider it misplaced. I would think he could summon up the dominant
wavelength of a Xerox lamp and correlate it to toner responsivity.

If an amateur had to relay a through a country and the amateurs didn't know each other language they still could have passed it by CW and the message could have been delivered to someone that could read it. Not no more.

When things start failing communication wise worldwide, amateur radio might be all there is to relay messages, and the ITU just removed one of the legs of a three leg stool.

And I assumed we were talking the energy of the photon.

By the way Richard, Wein's Law? We've long since learned that energy is quantized. E=hv That's how much energy is in a single photon at frequency v. (At least, that's what Einstein thought.) No fudging needed!

There are a lot of CW operators out there too. "A lot of ... out
there" doesn't seem to be the current criterion, does it? :)

Which is the point I was making - if we eliminate everything we don't
actually need for operation, the only things left are the laws and a
demonstration that we know how to flip the switch. Which would
probably suit the "let's eliminate the code entirely" crowd just fine.

>> so knowledge of the circuits inside a radio isn't
>> really needed. Nice if you want it, but not needed to operate.

>Circuit knowledge hasn't been NECESSARY for decades. Most kit radios of the
>50's (I build some Heathkits ,myself as a kid and helped my Dad with a few
>large projects) had excellent instructions.

But getting them to operate properly (except for that fiasco of a 2
meter transceiver they put out - the one that doubled as an aircraft
transmitter) took at least some little bit of knowledge. It was
really something that you could completely align a (then) modern color
TV set with nothing more than the parts in the kit (and you could
align it almost as well with them as you could with a shop full of
test equipment - I checked a few of them), but for most of the ham
gear you had to have some idea of how the circuits operated to get
them working really well. Not an engineering degree, but a little
more than the "theory" on the novice test.

(Granted, if a legally blind person could build a transmitter - K2TCF
built his Apache after he lost his visual acuity - and get it working
well, the Benton Harbor gang knew what they were doing.)

609. Re: Why is copper better than steel for wire antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-10 07:27:34 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <12imir75b8cq7c7@corp.supernews.com>
Source record: 51333

Either you didn't read the remainder of what I wrote, or I failed to explain it clearly.

I was speaking of antennas of a constant length in terms of wavelength as frequency is changed, for example half wavelength dipoles.

If you cut the frequency in half, the skin depth increases by a factor of the square root of two, so (assuming a conductor at least several skin depths in radius) the resistivity decreases by the square root of two. But to maintain a constant antenna length in terms of wavelength, the wire length doubles. So the total wire resistance at the lower frequency is greater by a factor of the square root of two. In other words, if you make two half wavelength dipoles out of the same diameter and kind of wire, and cut one for 1 MHz and the other for 2 MHz, the 1 MHz dipole will have about 1.4 times the resistance of the 2 MHz one. That's why you're more likely to see the loss of steel wire in lower frequency antennas.

Roy Lewallen, W7EL

>is quantized. E=hv That's how much energy is in a single photon at
>frequency v.

Yes, Wien's law was inappropriate for low frequency application
(meaning your daughter's computation is closer, by the factor I
offered, if not exact). His law was based on observational data for
very much shorter wavelengths. My studies generally confine
themselves well above 0ï¿½K, probably 2 or 3 degrees to a few hundred.
That is why I was initially satisfied with order of magnitude
accuracy.

> (At least, that's what Einstein thought.) No fudging
>needed!

Actually, Planck's explanation anticipated Einstein's photons by five
years. Further, he also corrected the massive errors of frequency vs.
power in what is called the Ultraviolet catastrophe. This was the
presumption that a Black body radiator emits energy with a
proportionality to frequency - a classical solution that yields
astronomic photonic power output at short wavelengths. I thought I
had dodged that bullet with my Wien's Displacement law spread sheet.
My focus is more oriented towards Phonon interactions.

To return to Gene's comment about the underlying presumption of Black
body radiation (perfectly correct), Planck's solution to the
Ultraviolet catastrophe was to describe Black body radiation as a
composite emission of many resonating cavities (which returns us to
single source Photons).

The pro-code arguments seem to be getting sillier and sillier.

I am a know-coder. I enjoy it. CW is my primary mode. I encourage others to
join in. I do not believe for one minute that CW is going to save the
world. I am not sure the FCC should be requiring it while not testing for
the various digital modes or message handling - seems inconsistent

Well, at least I educated you about top posting, and you are almost doing things the correct way now. I suppose that I should begin teaching you and others about TRIMMING your followups in order to make your posts easier to read. It's all there in the news.answers FAQs too, but lots of people haven't read the material.

The full content of all previous posts doesn't need to be quoted, because people have threaded newsreaders and can go back to read earlier posts without your help. Also, you'll save on that precious downloading time of which some of you spoke. People like Len Anderson and Dave Heil really need to learn how to TRIM their followups if they want anyone to read them.

I'll be checking back from time to time to see how you are doing. It looks to me like you're progressing well. There's definitely hope for you, so keep your chin up.

Slow Code you are pathetic. I think everyone on here is starting to
realize it. You are the jammer on the local repeater and you get on hf
and jam people because you cant have your way with the code
requirements. Face it nobody in the world cares what you think about
it. You make zero dirrerence in this world. Too chicken to post your
call because if you did you know what would happen. You have ruined
the newsgroups with your BS and soon you will be in everyones kill
file and fade away. Then you will just come up with another name like
No Balls or something. My suggestion to everyone is ignore this loser
from now on and let him get back to kerchunking repeaters and throwing
carriers on people on hf. You know thats the kind of trash he is.

I had a home made 1/4 wave ground plane vertical in the attic. Worked as
well as an Isopole on the roof. Gave away the Isopole. If you don't have an
attic, try the top of a closet. If you give up one radial, you can tape the
whole thing to walls and the front of the shelf.

Dear Mike (KU4YP):

This is usually an economics question. How much will you pay for the last 0.5 db of performance?

An alternative that I use is to use coax that has no more than 1 db of loss at the frequency in use.

With a tower of reasonable height that is over 100 feet away, it is unlikely that any 213 type coax is good value other than at 80 meters or below.

For receiving below something like 25 MHz, most any coax is good enough.

73, Mac N8TT

if you want to stop ham radio being dumbed down you need to turn in
your license and BAN the use of CW which has made mindless wrecks of
people like yourself I presonal don't advocate that course of action
but it is the way stop the dumbing down of radio

given the fact nothing in the written is go or nogo I don't meind it
being there although a great deal of the stuff their realy needs to go
(why does anything need to memeroze that frequency with in FS ATV that
is Black (or what ever color) there is NO need to know this at all
even if you are operating the mode

yes I would pare alot of stuff away from the current written and add
other stuff and certain reargange twhat is tested at what in the
licenseing structure (I would pull from the tech pool all the question
of skip since it is a minor factor at VHF and up ptu these question in
the genral pool

It's consistent with dropping requirements all around. Broadcast
stations no longer need licensed personnel on duty (that's been the
case for a few decades now), you can repair two-way radios without
being licensed and you can operate on the ham bands without having to
really pass any test.

funny I seem to recall taking a test and my wife took one a few months
ago for her license

of course you still can't tell me why it is important to know wether a
given circut is a colp[itts or hartley occilator

till you can explain what value knowing the name has you can begin to
convince me that you went a through a test as realavant as mine

Source record: 51351

Roy, W7EL wrote:
"Either you didn`t read the remainder of what I wrote, or I failed to explain it clearly."

The fault was mine, not Roy`s. It is true that if you scale an antenna for half the frequency by doubling its length without increasing cross-section of the wire, its resistance increases. Resistance is rho(l/a) where rho is the resistivity, l is the length of the wire, and a is the area of the wire`s cross-section.

Roy noted that lowering frequency by half means a wire twice as long which tends to double the wire`s resistance but skin effect increases penetration of the wire at the lower frequency. This reduces resistance by 1/sq.Rt.2. The same antenna using twice the length of the same wire but at half the frequency thus will have 1.414 times the effective resistance of the double frequency antenna.

Best regards, Richard Harrison, KB5WZI

The licensing hierarchy (and the morse code debate) isn't about value, it's about status. It's about having a chip on your shoulder that says "I'm better than you".

630. Modelling Antenna Factor of small loop

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-10 23:29:22 UTC
From: Owen Duffy <owen@no.where>
Message-ID: <ugaoi2l82f4t8r1ldgkq0h4porqcgh9p9k@4ax.com>
Source record: 51354

I am working on prediction of the Antenna Factor of a small square loop, and have created and run NEC-2 Models at a range of frequencies. The models are documented in the draft article at http://www.vk1od.net/SmallUntunedSquareLoop/ssulNEC.htm .

I would appreciate comments on potential pitfalls in the models that I have created. Should I expect an antenna built to the design to perform with perhaps tenths of a dB of the model?

It is if you think about it, -20log(Vout/Vin) vs log(Freq).

I am really interested in modelling accuracy issues like segment
length, right angle corners, load placement etc.

If a 12 year old can learn it I don't consider it much of a technical
skill. Nothing at all technical about CW. Building a transmitter, now
that takes somw technical know how.

Hi Owen,

I suppose so, however, when I see a sigmoidal curve, it begs a
different representation which, to me, reveals an underlying concept
(whatever that might be). Even with the redundancy of log
representation of a log value, its straight line representation may
worth consideration. I don't know why at this pass. This is just a
preference I would consider.

>I am really interested in modelling accuracy issues like
>segment length,

Generally self-driven by the results of successive modeling of
increased segmentation approaching an asymptotic level. The implicit
question would be: "Does the addition computational load warrant the
increased count?"

>right angle corners,

Area dominates such considerations, practicality is also significant,
results generally varies by little. As Reggie would offer, it is a
trade-off in the amount of wire, and spacing that would tend to
increase loss, and give rise to self resonance. He offered very good
advice on the size of coils, and this may have occurred before you
joined the group. I'm sure a review of his web page would reveal an
"unzipped" executable, but may lack the discussion he offered here.

>load placement etc.

An issue of balance (physical placement mimicking literal field
balance).

Richard

I'm not sure who you are responding to, certainly NOT the original poster. He can't put up a quarter wave, let alone an effing RHOMBIC!

I am amazed at how these threads can take off in only 3 responses into something that has absolutely nothing to do with the question that was asked.

One thing the newcomers to the group should know, and this information should be passed on on a regular basis, is that Richard is one of the most intelligent people here. Unfortunately, he is about the least helpful person here. He seldom answers questions directly, although he will try to pretend he is trying to make you learn something. He is not, he is simply showing you how much more knowledgeable he is than everyone else.

In this case the poster could not put up a quarter wave, and asked about putting up a long wire. Obviously if the poster couldn't put up a long wire, a flexible rhombic, which is absurd on the face of it, would be absolutely unacceptable.

I know we like to see straight lines in things, leads to simple
explanations.

I think a piecewise explanation of what happens here is:
- below the second knee, current is uniform and:
- below the first knee, loop inductive reactance is small, and
induced voltage is dominated by the changing freuency;
- above the first knee, induced voltage still varies with frequency,
but the loop inductive reactance is compensating that to a fair extent
and current (or loaded terminal voltage) is almost constant with
change in frequency;
-above the second knee, current is not uniform, reactance changes more
rapidly with change in frequency as resonance is approached, induced
voltage increases with increase in frequency.

The computation load isn't a big issue in these case, and I have
changed the segmentation with minutest change in results around the
current segmentation strategy.

Certainly, it can be solved from first principles at lower frequencies
where current is uniform, and as you say, area and self inductance are
the critical quantities. It is at the right hand end where current is
non-uniform that the NEC model becomes most relevant, and where I
depend on its accuracy... if I got things right!

> appreciated. Thank You.

I find it hard to imagine a 2M antenna that is easy to spot from a
short distance away. However, the first 2M antenna I made took 5 pieces
of copper wire, each 19 inches long, and a SO239 coax fitting (The
type used on a panel, that has 4 holes in a flange to bolt it on). Four
of the wires are bent at the end to make a short leg "L". the short leg
is poked through the connector flange and soldered. The remaining wire
is soldered into the center fitting of the connector, from the back.
This is now a "Ground plane antenna". if the four wires pointing out
from the connector are bent down at about 15-20 degrees, it should
match 50 Ohms, or near it.
Mine started life hanging from a light fixture in my bedroom, connected
to the transmitter with a short piece of Coax. With 3 Watts, I could
hit a repeater 30 Miles away.
Good luck- Bill-W4BSG

Hi Rod,

Strain relief, which, by the way, can be achieve by simply strapping
it to the tower.

Downside: creates a voltage standoff too in the event of lightning
strike. This is solved by the alternative offered in the paragraph
above (grounding implied).

I don't recall you mentioned that you were ALSO putting up a tower, so
IF, for example, your coax is running up the side of your house and
then across the roof, another answer is "to keep the coax in place"
vs. letting the wind slid it across the roof.

> coax standoffs. Are they necessary?

No. If somebody used standoffs for coax, it was probably money wasted.
Coax can be secured directly to the mast or tower, coiled on itself, and
even buried (some types). It could even be tied in loose knots without
having its electrical properties affected. You just can't crush it or bend
it tighter than the bend radius specified for the cable.

Open wire line and TV twinlead must be kept away from metallic structures
and not coiled. That's what you use standoffs for.

In a few cases, some form of standoff might be used when the coax forms a
rotor loop, but such use is strictly mechanical.

Another thing to consider is if the individual has a crank-up tower.
The rather longish "standoff" on the top of the upper section of the
tower is to keep the coax from getting fouled (and perhaps damaged) when
the tower is cranked down. However, on re-reading the original post, it
sounds like the question was about the little (6" perhaps) standoffs
which are typically used for twinlead...

[sigh] OH... That's different... Never Mind....

Thanks Walt, do you think I can do much with 20 watts. I undestand those
guys use max legal power and then some.

659. Wanting to examine mutual coupling

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-11 10:55:01 UTC
From: ryan.mitchley@gmail.com
Message-ID: <1160564101.622876.65640@m73g2000cwd.googlegroups.com>
Source record: 51233

Hi all

I'm doing some post-grad work involving antenna arrays.

I would like to compare my simplistic model (perfectly isotropic ominidirectional dipoles with zero mutual coupling) to a model that includes coupling effects. This is not the major focus of my thesis, but it's something I need to do, anyway.

I would basically like to get a handle on what kinds of phase differences (in degrees) exist between the two models, for certain frequencies and geometries.

I believe EZNEC may be capable of this (I have the demo)? Any other recommendations?

If anyone would be kind enough to walk me through an outline of what I'd need to do in EZNEC, I'd appreciate the help! (I am pretty new to finite-element EM modelling)

Thanks for any and all replies!

Ryan

660. dipole length vs db

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-11 11:06:23 UTC
From: ml <m@di.net>
Message-ID: <m-12FBAF.07062211102006@news.verizon.net>
Source record: 51234

hi

I ponder once again , and got a bit confused :

Currently i have a centerfed horiz dipole up pretty high

it's total length is less than 40ft, center feed via my sgc

i was thinking it'd be nice to have a SIGNIFICANT /real order of
magnatude type improvement in 'performance' or gain

my thought therefore went to making the dipole longer (as it's kinda on
the short side now)

so given the effort involved i wonder how much longer do i have to make
it to really extract a sig difference?

thanks

m

661. WTT - kenwood TS-440S w/AT for HF vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-11 11:56:37 UTC
From: John Schneider <thecop@optonline.net>
Message-ID: <VZ4Xg.20$tv5.9@newsfe10.lga>

I have a Kenwood TS-440S w/AT. The cabinet is an 8 out of 10 and the display is a 9.5 out of 10. I have the original owners manual as well. No mic. The radio was in service up to one week ago and worked very well.

I am looking to trade for an HF vertical in excellent condition, i.e. Gap Challenger, Titan, Cushcraft R7 or will consider Stepirr Vertical (+ cash, obviously).

Please email direct if interested.

Thank you,
John, KB2COP
thecop@optonline.net

Source record: 51236

There are lots of factors to consider here. On the bands where your antenna is longer than a half wavelength dipole, it will show gain over the equivalent dipole. If you keep it about 40 feet, it will have a single main lobe all the way up to 10m, where it's getting close to being an extended double zepp (two 5/8ths wave halves)

If you make it much longer, the pattern will break up into multiple lobes on the highest bands (which can, but not always will be, higher gain, but in weird directions, and there will be deep nulls)

Of course, the higher bands (10, 12, to a certain extent 15) are dead these days, so maybe we can exclude them from consideration.

- - - - -

The other thing to look at is the matching efficiency on the LOW bands. The antenna is very, very short for 160 and 80m and is quite short for 40m operation. The tuner, if it will give you a match at all, isn't going to be operating as efficiently as it could when you're operating on the lower frequencies. Lengthening the antenna would help that, and in that case, the gain could change a LOT, in the sense that you'd have a lot less LOSS.

So it depends on what you want to do. If you're doing a lot on 80m and 40m, and want to have a dipole-like pattern all the way up to 17m, I would suggest making the antenna maybe 74 feet total or so. This will still put the 17m main lobe broadside to the antenna like a dipole (though with some nonnegligible secondary lobes, but that's OK) and will do much better on 80m as far as the tuner's ability to match.

The multi-lobed nature on 15, 12, and 10 wouldn't ruin all operation there.

- - - - -

If you want to get gain in a particular direction using just a single wire, you need phasing sections, but that gain isn't all that useful unless you have a particular narrow direction that you favor, and your gain would be single-band anyway.

So what you gain by lengthening a straight wire is more that you'll have *less loss* on the lower bands, not so much that you'd get gain on the higher bands (though a 74 foot doublet does have about 2.5dB gain over a 1/2 wave dipole on 17m), and if you're trying to use a 40 foot dipole on, say, 80m, you could expect many dB of improvement by moving to a longer antenna.

Hi Jimmie,

I think it depends a lot on how high the noise level is. Son Bill, W2WM, in my town DeLand, FL, is using all Collins, 75A-4 rcvr and 32V-3 xmtr. He's been trying to get in on 3.80 MHz for several days--unsuccessful with 100 w input, but hoping. Son Rick, W8KHK, in Marietta, GA, also all Collins, with 75A-4 rcvr and 32V-2 xmtr, but not on the air with them yet. Hopefully next week.

Stay tuned.

Walt, W2DU

> --

One thing that has bothered me about small loop modeling. When
driven with a voltage source; loops of length < 0.1 wavelengths
exhibit a radiated power ,and efficiency, of < 0. In other words
the structure loss is > than the input power. Removing
the wire conductivity loading corrects the problem. In your
particular case, at 5 MHz, the real input impedance is
more than three orders of magnitude greater than the radiation resistance.
I guess it could just be numerical rounding errors, but have gotten
identical results when using double precision.

Hi Ryan,

It certainly is enough, given your stated goal.

>If anyone would be kind enough to walk me through an outline of what
>I'd need to do in EZNEC, I'd appreciate the help! (I am pretty new to
>finite-element EM modelling)

Open the file 4SQTL.EZ and select "View Ant," Once you appreciate
what you've got, select the button "FF Plot" to observe the
directionality. Select the button "Src Data" to observe the drive
point impedances. Select the button ">" next to the label "Sources"
to see their placement and phase.

If your designing becomes more elaborate and goes beyond the demo 20
segment limitation (not a problem with the file suggested here), you
may want to buy the package.

Hi Ryan,

Right advice, wrong file. In addition to the advice previously
offered, open file 4SQUARE.EZ and repeat instructions. The two files
lead to the same outcome for the same reason. The difference is this
file reveals how to do it with 4 sources.

This, by the way, gives you all the characteristics you asked for such
as mutual coupling. So does the first file, but this one is probably
more illustrative for revealing the drive point Zs and how that mutual
coupling affects them.

Move the single elements around and observe the full effects and
outcomes.

Geoff Mendleson offered some good advice.
The dipole he suggested can be made using one 19-inch whip as the upper half of a vertical dipole and a 19-inch metal tube as the lower half of the dipole. The tube is also used as a sleeve over the coax which feeds the dipole at its center.

This antenna is often called a coaxial or sleeve antenna. It is also often disguised to appear as something else such as a flagpole, etc. This antenna has 0 dBd gain and is omnidirectional in the horizontal plane. It works well in almost any line of sight direction and so is useful with portable and mobile stations. It is as good as a ground plane antenna without projections to cause injuries.

Best regards, Richard Harrison, KB5WZI

Had a good time playing with my grand niece and grand nephew
in TN whose IQ's are impossible to measure in public schools.
It runs in the family. :-)

Back to the present thread. I infer that you believe
that Hecht's total irradiance equations are in error?
Before you reply, let me remind you that Dr. Best was
the first one, to the best of my knowledge, to publish
the irradiance equations in an amateur radio
publication, QEX.

In the following fixed font diagram, IR is the Index
of Refraction.

```
air | 1/4WL thin-film | Glass
1W Laser---IR=1.0---|----IR=1.222-----|--IR=1.493---...
Ifor=1W | Ifor=1.0101W | Ifor=1W
Iref=0.01W | Iref=0.0101W | Iref=0
```

Note that I is "irradiance", not current.

Given: The irradiance reflection coefficient is 0.01
at both interfaces. The irradiance transmission coefficient
is 0.99 at both interfaces. Please describe your theory of
the wave cancellation process occurring at the air to thin-
film interface without using the superposition and interference
principles that I have been using to which you object.

The advantage of using a whip and tube are the much wider bandwith than
with a wire antenna. However if you are really stuck for places to put
it, two 19" pieces of wire will do. Since most people only use a few
watts on 2m FM, then the thinnest wire you can find will probably do.

> This antenna is often called a coaxial or sleeve antenna. It is also

I think someone sells one that is a plastic pipe you slip over a vent
pipe.

If you are allowed TV antennas, you can build a "CIA special" which is
a 2m and 440 beam fed by 300 ohm twinlead. On HF, the twinlead becomes
the antenna and the beam part a capacative hat.

I hid a J-Pole made of 300 ohm twinlead in side a white plastic pipe.
If you use thin enough coax to feed it, it can be used to support all
sorts of things, a pin-wheel or wind speed gage for example.

73,

Geoff.

Perhaps, should I have used the term, "reflectance"?
Allow me to refer you to page 120, "Optics", by Hecht, 4th
edition, equation for reflectance, R, "ratio of the reflected
power to the incident power". (References are a bitch to
deal with, huh?) Note that reflectance, irradiance reflection
coefficient, and RF engineering's power reflection coefficient
are all the same thing.

thanks very much for taking the time to help me out dan, appreciate it

some of what you wrote sorta confused me, and maybe some left me
wondering still

i see what you ment about adding length improving the lower frequencies
80m i am 'ok' with that

but if I made the antenna length for ex 74' it's 'bad' or sort of less
than ideal things would happen on say 10m??? meaning it would be
'too' long?

so my goal here was an extreem gain 2orders of magnatude at least i
sorta thought that perhaps a wave on the lowest freq (160)might be
ok, but i get confused on how say that would negatively effect 10m

as the lobes increse their the penality is lots of nulls and radating
in odd directions?

so if i was listening to 10m and a sig was comming in on my existing
antenna say s9 and i made the antenna 74ft the signal would be lower?
maybe?

if this is true to get an 'optimal' all bad dipole you'd have to have
say 2 of them a 160-40 another for the rest?

just a little confused

I don't know if we'll get Mad right away but it's clear the FCC and the
ARRL want to drive all good hams out of the service. Little by little
they'll take away the non-phone portions of the bands and hand it over to
the phone users. Like a frog in a pot of water that's raised to boiling
point, one day us real hams will find we have to place to communicate on
the ham bands that doesn't sound like Citizens Band.

But the written tests have been dumbed down as well. You don't need to
answer as many questions over-all for the General and Extra as you used
to.

I emailed President Bush he should kick out all the Bill Clinton Liberals in the FCC after he got elected, but he didn't. I can't blame him though because he choose to tackle the terrorist mess Bill Clintoon left the country instead. I feel a lot safer now than I did under Clinton, and the economy is better too.

I just wish all you people would take a stand against dumbing things down any further. If it continues, it going to make hams irrelevant and our bands will sound like CB.

Well if it's not a problem to learn, let's keep the requirement and raise
it to 13WPM. It's a bit boring doing code at 5 words per minute, and at
13 WPM you can copy someones call for help almost three times as fast.

I'm sorry Opus, but I refuse to lie. You did get a hand-out, and you're
Lazy because you refuse to learn CW to 20wpm, and too lazy to to use it.
You don't want to be a good capable communicator in every way. That's just
how it is. I'm sorry if the truth seems like an insult. You're right
about one thing, I spelled Kanada wrong, I meant to type KKKanaduh. Eh.

hams will tend to study the theory more while they build up their
code skill and they will understand the theory better and won't need to
ask silly questions\

There are no silly questions, really. I mean no one is born knowing
stuff. If you don't ask how will you ever know?

> 'too' long?

Too long for what? Horizontal long wire antennas have
certain radiation characteristics. Consider the rhombic.
Some say it's the best antenna in the world.

> so my goal here was an extreem gain 2orders of magnatude at least i
> sorta thought that perhaps a wave on the lowest freq (160)might be
> ok, but i get confused on how say that would negatively effect 10m

> in odd directions?

Sometimes "odd" directions are the best if that's the
direction of your desired contact.

My own 130 foot dipole works like gangbusters on 17m.
It has 8 lobes each at about 8 dBi with a take-off-
angle of 19 degrees.

> so if i was listening to 10m and a sig was comming in on my existing
> antenna say s9 and i made the antenna 74ft the signal would be lower?
> maybe?

Maybe lower but maybe higher. Unknown directions for
horizontal antennas may be good.

The g5rv designer, Mr. Varney, deliberately designed his
20m dipole to be "too long" because he desired the multi-
lobed radiation pattern.

Name one real/valid/probable scenario for this. Let me guess, you crash land on the moon, have only a D-cell battery, some wire, a butter knife, happen to find some crystals, some silicon, somehow beyond your knowledge or abilities, manage to build a transmitter, and send your SOS back to Earth. Is that about right? Nah, you'd die trying to make it iambic.

thanks cecil, i kinda didn't fully understand some things in dan's post
my overalll takeaway was that just adding length to the antenna might be
'bad' ie not really garantee full band tremendious signal improvements
160m-10m in the same direction as i radiate now (mostly e-w) from his
post maybe he might add a few more comments to see how i can add
length and non direction gain to my setup on the higher freq side as
well as the lower

but i understood what you wrote cecil

i think for me to just try it might be most fun perhaps w/a switch

>> Ifor=1W | Ifor=1.0101W | Ifor=1W
>> Iref=0.01W | Iref=0.0101W | Iref=0

The reflectance (irradiance reflection coefficient) at
the air to thin-film interface is
[(1.222 - 1.0)/(1.222 + 1.0)]^2 = 0.01

The reflectance at the thin-film to glass interface is
[(1.493 - 1.222)/(1.493 + 1.222)]^2 = 0.01

1% of the irradiance is reflected at either surface and
99% of the irradiance is transmitted through the surfaces.

Would you like to engage in a technical discussion of
how non-reflective glass works or would you like to
keep avoiding that technical discussion?

Your memory must be failing you, Cecil, as it was I who originally explained to you how anti-reflective coatings work and provided you with the Melles-Griot web site, the irradiance equations, and several references on the subject. I know how these coatings work. I have the optics bible, "Principles of Optics" by Born and Wolf sitting on my desk right here in front of me, and have referred to it frequently during our many previous technical discussions on the subject. Your pretense here is ridiculous.

I hadn't seen the one with a 'forward laser power' reading, as if he
was reading it from an SWR meter before. Seems suspicious.

I have presented that example before. You chose not
to discuss it back then. The output of the laser is
given to be one watt. What's so suspicious about that?
Whatever laser one buys comes with a power output
rating.

If we discuss this example, step by step, you can show
me, once and for all, the error of my ways.

Cecil,

I don't have a copy of Hecht. Like Jim, I use Born and Wolf as a "textbook" reference and several other books for practical optical design reference.

Does Hecht really say that more power goes into the glass than enters the 1/4WL film? Can we somehow bottle this free energy and save the world?

By the way, those irradiance equations go back a couple hundred years. It seems unlikely that Dr. Best was the first to publish them, even considering only amateur-oriented publications.

Top posting makes this very confusing.

However, I am convinced that nobody in industry or at the FCC cares about anything other than optimizing short-term revenue. The notion of optimizing spectrum use for the greatest good went out with the Carter administration. This is one of the greatest tragedies of our time in my opinion.

No, and neither did I. The 0.01W of power reflected
in the diagram undergoes destructive interference.
That's why they call it "non-reflective" glass.
The 0.01W is known as the external reflection. There
is a matching 0.01W (not shown) from the internal
reflection that causes wave cancellation. All of this
is explained in any good physics book. If anyone is
willing to go step by step with me, I will either prove
my point or be disproved in the process. What I cannot
figure out is why everyone is avoiding a step by step
technical discussion and instead engaging in ad hominem
comments - hoping to prove what?

> By the way, those irradiance equations go back a couple hundred years.

Well, I said that was to the best of my knowledge. I
had never seen Ptot = P1 + P2 + 2*SQRT(P1*P2)cos(A)
in an amateur radio publication before and I have
been reading them since 1952.

722. Half Square question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-12 18:42:23 UTC
From: "JimK2TL@gmail.com" <JimK2TL@gmail.com>
Message-ID: <1160678543.641013.293570@k70g2000cwa.googlegroups.com>
Source record: 51196

I have been researching the HSQ antenna until I am Half Crazy.. anyway,
I am looking for info on this article: "Rotate the Bobtail Curtain";
Jerrold A. Swank, W8HXR; 73, May 1985, p.48 , A clever method of
switching the half square's pattern to end fire using a quarter wave
stub. I found a reference to this on a web site.
I can't seem to find this info anywhere. I am very interested in
this because the way my property would accommodate a HSQ antenna would
put it broadside NW by SW..not exactly a DX friendly direction from New
Jersey.
Does anyone know what this technique is and how to build it?

And I hope you don't mind if I ask a few more questions. I am
inclined to voltage feed one vertical wire with an LC network, but I
have read a lot of posting saying that this is blasphemy and it MUST be
fed at a corner with coax or your soul will be doomed. I hope not !
Is there a final opinion on this? It seems to me that corner feeding
has more problems associated with coupling to the coax line than
building a simple LC network. But then, do I need a radial system for
voltage feeding?

Thanks for any help on both these questions.

Jim

ML-

I have a similar question, but I'm not looking for a "real" order of magnitude improvement. I just want to get on the air.

If I only have room for a short dipole, say 40 feet, and use a tuner such as the SGC or Icom AH-4, what is the penalty in DB for the lower bands (160, 75, 60, 40) compared to a half wave on each band?

Voltage feeding works just fine. Radials won't do a lot
of good because the current maximum points are at the
top of the antenna, not at the bottom.

Hi Gene,

Isn't this the point at which all should simply surrender to accepting
69% error as being sufficient for a proof? No one here really expects
Cecil's dy-no-mite advantage to be set aside for the sake of accuracy
- do they?

However, your question illuminates the necessity of Cecil being the
one to ask "Where Does the Power Go?" That redeems the thread's
entertainment value.

Don't know the dB but losses would be appreciable. Why not
put up a 22 foot vertical with a good radial system? That
will work pretty well for 40m-10m using the autotuner at
the base. Install a base loading coil and it will work
reasonably well on 75m. Can't say much for 160m.

Hi Fred,

Good, simple antennas are not going to show an "order of magnitude"
improvement under any circumstance short of issues related to loss.

>If I only have room for a short dipole, say 40 feet, and use a tuner such
>as the SGC or Icom AH-4, what is the penalty in DB for the lower bands
>(160, 75, 60, 40) compared to a half wave on each band?

What do the manufacturers say? OK, they probably guarantee nothing
other than a match (I am familiar with the local manufacturer's claim
of loading a wet string.)

The radiation resistance of a 40' dipole in the 160M band is 1 Ohm.
The contribution of loss resistance in proportion to this reveals
efficiency/loss. If anything in those boxes contributes as much as 1
Ohm, then you are down by 3dB before the signal hits the airways.

The only question is can that additional 1 Ohm contribution dissipate
the heat without self destruction? Think about it, 50W of heat inside
that box. The manufacturer would probably guess correctly that you
would never feel it, unless you are working RTTY.

An additional 1 Ohm attributable to the manufacturer's designs may be
an outlandish assertion. Again, consult their specifications.

Gene, here's a complete fixed font irradiance diagram of
the air to thin-film interface including all components.
Reflectance = 0.01, Transmittance = 0.99

Forward irradiance component

Ifor=1W -->|
|--> I1=0.99W
I3=0.01W<--|

air | thin-film

Reflected irradiance component

|<-- Iref=0.0101W
I4=0.01W<--|
|--> I2=0.0001W

I1 + I2 + 2*SQRT(I1*I2) = 1.0101W = Ifor in the thin-film
This is "total constructive interference" per Hecht.

I3 + I4 - 2*SQRT(I3*I4) = 0W = Iref in the air
This is "total destructive interference" per Hecht.

Those are the irradiance equations from "Optics", by Hecht.
As Hecht asserts, the destructive interference equals the
constructive interference and the reflections toward the
source are canceled.

Not exactly as per Hecht. Note to the casual reader: please be advised that unlike Cecil, Eugene Hecht does not claim that power is equal to irradiance. Nor does he imply that scaler quantities can be treated mathematically in the same way as vector quantities, and he therefore does not substitute power for irradiance in any of his textbook equations as Cecil has want to do.

These equations do in fact give correct results macroscopically. However, it is inaccurate to infer from interference equations that a given electromagnetic wave is 100% reflected from any partially reflecting boundary. It is only after multiple partial reflections from the inner boundaries of the intermediate medium that the total energy from any given wave in conveyed from source to load.

It's only fair to tell everyone reading your posting that
you do not accept the definition of power in the IEEE Dictionary
nor the definition of power used by the average RF engineer.
Irradiance, Poynting vectors, and power flow vectors are valid
concepts no matter what esoteric definition of power that you
choose to assert.

Hecht gives the dimensions of irradiance which are the same
as the Poynting vector (power flow vector) in RF engineering.
That you don't consider watts to be power is no reason to
question the validity of irradiance or Poynting vectors.
I don't have "Optics" with me at work so I cannot do an
exact Hecht quote.

> Nor does he imply that scaler quantities can be treated
> mathematically in the same way as vector quantities, and he therefore
> does not substitute power for irradiance in any of his textbook
> equations as Cecil has want to do.

I am using Hecht's irradiance equations. Whatever Hecht
implied by those equations is exactly what I am doing. Any
angle used in the irradiance equations is the angle between
the electric fields of the two superposed waves.

It was not me, but Dr. Best, who first substituted power for
irradiance in his series of QEX articles. But Poynting vectors
can obviously be substituted for irradiance since they represent
the same thing and have identical dimensions. Most RF engineers
would assert that Poynting vectors and power flow vectors represent
power. It is your narrow definition of "power" that is the culprit
here, not anything I have said.

If it will make you feel better, forget the power equations and
call them the power flow vector equations. I will try to remember
to do that in the future.

All the values are average *steady-state* values, the same values
that would be read by a Bird directional wattmeter. All multiple
reflections are rolled into the average Iref value displayed by
the Bird. All multiple forward components are rolled into the
average Ifor value displayed by the Bird.

Hi Frank,

That is interesting.

I haven't pursued modelling the loop being excited directly, but I
accept your observations.

I have no idea what causes the problem. Perhaps a NEC guru may have an
explanation?

I thinking about the impact of error in the estimate of either
radiation resistance or loss resistance of the conductor in the
scenario that I did model, it should be low, probably insignificant.
The magnitude of both components is small relative to the load
impedance and the loop's own reactance, and does not influence the
loop current (and therefore the load voltage) much.

Whilst it would be interesting to know if it is a fault in modelling,
or just numerical stability in the computation engine, I suspect the
effect you observed probable does not give great concern for the
accuracy of my receive loop models.

I would like to have modelled insulated wire in the loops, but don't
have NEC-4... so I will build the loops from bare wire, although I
think it would make very little difference, even more so at the lower
frequency side of the range.

Thanks, appreciate the thoughts.

Owen

To say the least. For a loop with sides of 1 meter, the radiation
resistance at the low end of the chart verges on 150 nanoOhms. If
this were copper wire, it would exhibit about 2.5 Ohms per 1000 feet.
Instead it is steel wire (about 5 to 10 times the resistance) over a
length of 13 feet or so. I will be generous and call it half an ohm
total.

>>Removing
>>the wire conductivity loading corrects the problem.

I hope you don't pack your own parachutes!

You might want to revisit those thoughts.

>The magnitude of both components is small relative to the load
>impedance and the loop's own reactance, and does not influence the
>loop current (and therefore the load voltage) much.

What you are saying is the antenna is a voltage source, and power efficiency can go to the devil. For receivers, they forgive such blasphemy. Just how much appears to be unknown at this point (we will say things are in limbo). However, if you add a capacitor, you should be able to observe the loss in the expressed Q. This is an untuned loop, is it not? Somewhere there's the devil to pay otherwise. }:-)

>Whilst it would be interesting to know if it is a fault in modelling,
>or just numerical stability in the computation engine, I suspect the
>effect you observed probable does not give great concern for the

Turning the antenna into a voltage source gives rise to many nuances that would otherwise be smothered.

>

You don't need to use all of the antenna. If you only need half or a third just use that. I have an old cushcraft aop-1 and when I need to go compact I just remove the screw holding sections of the 2m boom together and use half of it. The 70cm side of the aop-1 is short so I don't mess with that.

When you sit down at a VE test session the number of questions you have to
answer over-all to be a Tech, General, or Extra class is less than it used to
be and that's not including the questions lost when CW was dumbed down.

Everyone that desires to be a good ham and valuable asset to the radio
service and to their country do.

Now how's your CW practice coming along? Are you practicing or did you
decide to pack it in and just talk on a mic like other lazy KKKanadians.
Eh?

KKKanadian licenses are all hand-outs now, just like your health care system, but that's not your fault and I don't blame you for it. Still, if you want to be a real ham you might want to get your code speed up so you can communicate with other real hams. We'd love communicating with ya.

It's clear the FCC and the ARRL want to drive out all good hams from the service. Little by little they'll take away the non-phone portions of the bands and hand it over to the appliance operators. Like a frog in a pot of water that is raised to boiling point, one day us real hams will find we have no place to communicate on the ham bands that doesn't sound like CB. Apparently, I'm the only one seeing it coming. A ham who will stand for nothing will sit for anything.

756. Here the R&O-- FCC if interested.

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-13 00:54:47 UTC
From: Jim - NN7K <NN7K@NOWAY.NET>
Message-ID: <rtBXg.13555$e66.13064@newssvr13.news.prodigy.com>
Source record: 51130

To all radio amateurs

SB QST ARL ARLB019
ARLB019 FCC releases long-awaited ''Omnibus''
Amateur Radio Report and Order

Ending a protracted waiting period, the FCC's
Report and Order in
the so-called ''Omnibus'' Amateur Radio
proceeding, WT Docket 04-140,
was adopted October 4 and released October 10,
2006. In it, the FCC
adopted nearly all of the proposed changes in the
Notice of Proposed
Rulemaking released back in 2004. The FCC has:

+ expanded the phone subbands in the 75 and 40
meter bands;

+ permitted auxiliary stations to transmit on
portions of the 2
meter band;

+ permitted the use of spread spectrum on 222-225 MHz;

+ permitted amateurs to retransmit communications
from the
International Space Station;

+ permitted amateur licensees to designate a
specific Amateur Radio
club to receive their call sign in memoriam;

+ prohibited an applicant from filing more than
one application for
a specific vanity call sign;

+ eliminated certain restrictions on equipment
manufacturers;

+ permitted Amateur Radio stations in Alaska and
surrounding waters
more flexibility in providing emergency
communications;

+ clarified that ''amateur stations may, at all
times and on all
frequencies authorized to the control operator,

make transmissions
necessary to meet essential communication needs
and to facilitate
relief actions'';

+ deleted the frequency bands and segments
specified for RACES
stations;

and

+ deleted the requirement for public announcement
of test locations
and times.

In addition, the FCC took several other
miscellaneous actions.

In ''refarming'' the frequencies currently
authorized to Novice and
Technician Plus licensees, the Commission
increased the voice
segments for General, Advanced and Amateur Extra
licensees.

On 75 meters, Generals will be able to use voice
from 3800-4000 kHz,
an increase of 50 kHz. Advanced class licensees
will be able to use
voice from 3700-4000, an increase of 75 kHz, and
Amateur Extras will
be able to use voice from 3600 to 4000 kHz, a
generous increase of
150 kHz.

On 40 meters, Advanced and Extra Class licensees
will be able to use
voice from 7125-7300 kHz, an increase of 25 kHz.
General class
licensees will be able to use voice on 7175-7300
kHz, an increase of
50 kHz.

On 15 meters, General class operators will have
phone privileges on
21275-21450 kHz, an increase of 25 kHz.

ARRL President Joel Harrison, W5ZN, expressed the
ARRL's gratitude
to the FCC Commissioners in a letter dated October
11: ''On behalf of
the ARRL and the Commission's licensees in the
Amateur Radio Service

I want to express appreciation for your release
yesterday of the
Report and Order in WT Docket 04-140 (FCC 06-149)
amending Part 97
of the Commission's Rules. The Commission's action
in clearing this
pending proceeding will assist the Amateur Radio
Service in meeting
its objectives, particularly with regard to
providing emergency and
public service communications.''

The changes will go into effect 30 days after the
R&O is published
in the Federal Register.

The 1 watt laser mental exercise is my idea. Everything
else is directly from "Optics", by Hecht.

A 1 watt ideal laser was chosen for its single frequency
and coherent characteristics to avoid any more "brighter
than the surface of the sun" postings.

Why are you afraid to discuss a 1 watt laser?

"Slow Code" does not know what code speed "Opus" can do. He simply
assumes.

Note that we do not know "Slow Code's" code speed, either.

> >You don't want to be a good capable communicator in every way. That's just

>You might want to revisit those thoughts.

I have also created a (non NEC) model that depends on the assumption that current is uniform. Frank has commented on a NEC model at 5MHz, where the loop side is 0.016 wavelengths, so current is close to uniform. Using that frequency in my non NEC model suggests that the radiation resistance is 0.0026, conductor loss resistance is 3.07, loop inductive reactance is 163, and the load is 50. The circuit impedance is 53.07+j163, and load voltage is relatively insensitive to small changes in radiation resistance or conductor loss resistance.

The model is at http://www.vk1od.net/SmallUntunedSquareLoop/temp/1.htm
.

Changing the NEC model to be driven by a voltage source, I get loop Z of 3.63+j173, so NEC predicts a higher loop Z. The efficiency calculated by NEC is 1.54%, much lower than the 0.085% implied in the simple model. The NEC efficiency implies that radiation resistance is 0.055. Doubling the number of segments in the NEC model does not markedly change loop Z, but increases efficiency to 2.3%, so there is something strange happening in the way it determines radiation resistance. With a single segment per side, NEC suggests efficiency of 0.8% which is close to my simple model.

One of the data points from my NEC2 run is at 5.091MHz, and Antenna Factor for the loop and 10m of RG58CU is 30.624dB/m. That includes an amount of the coax loss, and that amount should be 0.309dB, leaving the loop itself at 30.316dB/m.

> > Fred
> > K4DII
>
> just a fyi, this really belongs in a new thread

ML-

Perhaps you are right. I was attempting to ask the same question in reverse: The "penalty" is the opposite of the possible improvement.

So far I've learned that the majority of loss is in the matching network. Actual gain of a shortened dipole is only about a half dB down, but radiation resistance is so low that I-squared-R losses in the tuner are significant.

Someone mentioned that you could reduce losses in the tuner by adding external loading coils. It seems to me that you would just be moving the loss out of the tuner into the loading coils.

The question of whether an order of magnitude of improvement can be attained appears to be answered. If you define that as ten dB of improvement, then probably not. The total penalty is most likely less than that.

73,
Fred
K4DII

You are right that the gain of a short practical dipole is good (and that requires that the losses are low).

The transmission line is a potential source of high loss when feeding a short dipole.

There was an article on QST some time back on using a 66' dipole on all bands. I have written a review which contains some graphs that cast light on where the losses are, the article is at http://www.vk1od.net/LOLL/index.htm .

It turns out that for most practical configurations, it is difficult to achieve good overall efficiency when the dipole length is below about 35% of a wavelength. You will probably need parallel wire transmission line rather coax for a shortened dipole.

Taking an "order of magnitude" to mean a tenfold increase or decrease (10dB), it will be challenging to improve an antenna tenfold by just adding length unless it was very inefficient in the first place (too short, lossy feedline + ATU).

If you coax centre fed a 40' dipole on 3.6MHz with 30m of RG58, you would find opportunity for tenfold improvement by increasing length (to a particular value).... but only because it was so hopelessly inefficient as configured.

By my 35% suggestion, a typical parallel line centre fed 40' dipole will peform ok down to about 8.6MHz. If it is coax fed, it will only be reasonably efficient on its series resonances (~12MHz, ~36MHz).

Hi Fred,

The advice is good, and the logic demands you consider what you say.
What is being exported is the inductance and if you are good at it,
you can build a loading coil that exhibits less loss than the
inductance internal to the tuner.

This reduced loss comes about by larger wire, larger form factor, more
spacing between turns:
Larger wire has more surface area which is significant for skin
effect.
A larger form factor will allow more inductance to replace what is in
the tuner (it will not be a 1:1 even trade, however).
More spacing between wires takes us back to skin effect. Wires that
are in proximity closer than 3 diameters will force currents beneath
the surface of the wires (magnifying the skin effect's loss through
reduced volume for current).

Another virtue is that loading away from the tuner, up in the
structure of the radiator, allows a higher current to flow in that
structure. The general advice is to put the load at least 1/2 up to
2/3rds away from the feedpoint. Outside of this region has
diminishing results. THIS is where you will find gain over a bare
wire and for very short wires, that gain CAN be an order of magnitude.

ml,

I think the other posters have covered the fact that you just can't get an order of magnitude or two over all bands just by lengthening the wire. Two orders of magnitude, or 20dB gain over a dipole requires really heroic effort in antenna building at HF. If you put a lot of time, money and effort into it, you might be able to get 20dB gain over a dipole on 10 meters. You would have to use stacked long-boom beams or something of that sort.

Even 10dB gain over a dipole is going to require a big beam. Think 5 element yagi or so. So, unfortunately, you're not likely to get a gain of more than a few dB over a dipole... maybe 5 or 6dB, like Cecil's antenna on 17m, which is a substantial gain, but falls short of an order of magnitude.

Cecil's point is valid. I went a bit overboard on saying that the pattern of a long dipole was BAD. The multiple lobes can be useful if they point in the directions you want to work, it's true.

It IS bad if there happens to be a null on a station you want to work. It's good to be able to put the energy you're radiating in the direction you want.

For a long multiband antenna you can't rotate, this could be hard because the direction of the peaks and nulls changes with frequency. This could be good, it could be bad, but without pictures, you just don't know which way your signal is going. (you can find some pictures of long doublet patterns here, by the way: http://www.cebik.com/wire/abd.html.)

- - - - - -

Something to think about regarding massive signal improvement from changing your antenna: Having a high gain antenna means that you get response in the direction you want *at the expense* of other directions.

This is why high gain ham antennas are made rotatable. You can send all your transmitted power in a narrow *beam* in the direction you want to work.

For a very long doublet, the lobes may have gain over a dipole, and that could certainly be useful for some contacts. It could be, though, that you have a null in the direction you want to work. In the end, that probably all averages out.

- - - - - -

If the multiple-lobed pattern works for you, just make the antenna 1/2 wavelength long on the lowest frequency of operation. This will give you a big EFFICIENCY boost on the low frequencies, because less of your power will go to heat in the tuner.

I wonder, also, how high your antenna is above ground. Putting your antenna higher will improve the signal on all bands, possibly dramatically on the lower frequencies if it's not up at least an eighth to a quarter of a wavelength on the lowest band.

You might just try to build something for a single band where you want improvement. That's what I did when I was starting out. I had a 150 foot wire that I used on all bands, but then I started building single band antennas for my favorite bands to improve performance there.

Some quasi-wild guesses for a 40 foot dipole relative to full size at
the same height, probably best case.

160m: -16dB
75m: -8dB
60m: -3dB
40m: -1.5dB

These numbers don't mean much. I used EZNEC to look at the losses in
Q=100 loading coils with enough reactance to bring thing to resonance
on each band. No attempt to match to 50 ohms was made, but I made the
Q kind of low to reflect other tuner losses. Still, these are almost
certainly optimistic, especially on 160.

Dan, looking at a hypothetical unloaded scenario...

I don't know what feedpoint Z you got for a centre fed 40' dipole at
7MHz... but lets guess somewhere about 11+j750. Lets feed the antenna
with 15m (~50') of RG58C/U for a loss of 18dB (efficiency 1.6%) and an
input z at the ATU of 44-j179. The ATU should handle that with very
low loss... so overall, the efficiency is ~1.6%.

You can do these calcs with the line loss calculator at
http://www.vk1od.net/tl/tllc.php, nothing to unzip!

Adding 26' of wire to the dipole should improve the antenna to better
than 80% efficiency or a fifty fold improvement on transmit. But it
only worked so dramatically because the 40' dipole centre fed with
coax is so inefficient.

Owen

Very little radiation occurs before the tuner.
Lots of radiation often occurs between the
feedpoint and the loading coils.

Jim Kelley wrote:
> Not exactly as per Hecht. Note to the casual reader: please be advised
> that unlike Cecil, Eugene Hecht does not claim that power is equal to
> irradiance.

Here's a quote from "Optics", by Hecht concerning irradiance.
"... since the *power* cannot be measured instantaneously, the
detector must integrate the energy flux over some finite time,
T. ... The time-averaged value of the Poynting vector, ..., is
a measure of I." - where I is the irradiance and the Poynting
vector is the power flow vector.

Hecht seems to treat irradiance the same way that RF engineers
treat power flow vectors. Hecht also says that integrating energy
flux over some finite time is a measure of power. Presumably,
that could be a non-destructive mental integration.

In "Optics", the definition of irradiance is: "the average energy
per unit area per unit time". That's the same definition as the
power flow vector from the IEEE Dictionary: "... *power* per
unit-area propagating in the wave".

Also from the IEEE Dictionary: "Poynting vector - ... The integral
of P(t,r) over a surface is the instantaneous electromagnetic
power flow through the surface."

Do you really think Hecht used the Poynting vector while ignorant
of its definition?

When an astronomer draws a spherical boundary around the sun and
calculates the power output of the sun, most of that power is
heading out to empty space and doing no work. Maybe you should
campaign to have that calculation removed from publication.

thanks for the tips appreciate your time in writing the posts :)

my antenna is about 150ft high and rather higher above average terran
i am up on a naturall high spot almost a hill the view from the roof
is amazing only 1 other building is taller than me for miles

i had thought i dunno why that if i ended up w/a dipole that was very
long (multi waves) i would get increased gain(significat) at some point
but i certainly dont want to end up w/directional gain i wanted a broad
freq and broad radation since i like to work all bands and all
locations

so i learned i still can't have my cake and eat it too <stomp>

i'll prob just follow cecil's and richards' rule, of build it and
experiment i'll end up w/a 160m long dipole as it's my lowest freq and
see how it goes i'll have to call my tuner manuf as i don't think it
will tune that long perhaps i can modify it or i'll have to use a tuner
in the shack

then i'll just see how it works i guess ok on the lower part but up
around 10m if i understand it i'll become more directional

an a/b switch and i'll be set

i'll have to figure what wire ga will support itself at that length 2
160m runs is big i can support it in the middle on one side but the
other is free

thanks very much i really did learn alot

m

Hahaha... guess you need a complex conjugation checker. Owen, I was assuming no feedline and an antenna tuner at the feedpoint and being very gracious towards that antenna tuner's abilities (I wouldn't be surprised if a tuner could match 11-j750 with 1.5dB of loss, though maybe not a 100W-class autotuner).

As far as the transmission line calculator goes, I use it ALL the time. It's a fantastic resource, both technically and ... well, rhetorically. A lot of folks will say their antenna works even if their antenna is a 40 foot dipole fed with 50 feet of RG-58 on 40m.

They can hear people with it, their rig's autotuner loads it up just fine on 40m, and they can "make contacts" but their effective radiated power is going to be 1.6 watts... and feedline loss is an environmentally-unfriendly way to be a QRP operator.

Dan

For the 160m band, the antenna only needs to be 80m long.
The rule is: Make the dipole 1/2WL long on the lowest
frequency of interest. And actually, using a tuner, you
can get away with making it 3/8WL long on the lowest
frequency of interest. So your dipole only needs to be
~60m long to cover 160m-10m.

The ATAS-100 is a good antenna using a rubber boot for coil protection. Had a few reports about water getting into the rubber boot causing corrossion problems internatlly, which could be repaired.
The ATAS-120 was a remake of the ATAS-100 BUT used a metal coil protector that avoided the water damage problem.
I've used both and both work the same way. If the ATAS-100 is available at a "really" good price, would ensure it operated OK, and would not leave it on the vehicle 100% of the time...just install it as you need it during a trip. Therefore avoiding any water damage, which apparantely only occurs during a rain storm while driving.
A nice Antenna for the price, but would like to compare it to a larger diameter coil model.

I have been offered a used Yaesu ATAS-100 mobile antenna. Not knowing the differences with the newer ATAS-120, I am not sure whether it would be worthwhile to spend (considerably) more money on a new ATAS-120. Does anyone have information at that regard?

I'm in the middle of building one. I'm planning on about 50 radials
per vertical. To save wire I will probably shorten the radials "inside"
the array and connect them to bus wires.

The radial-laying sure is taking a lot more time than putting up the
verticals :0

I don't know about the stub article, but voltage feeding was what made
the Bobtail Curtain such a great antenna. No radials needed. As I
recall, all I had was a short ground rod and a parallel tuned tank at
the bottom of the middle vertical element. A fun antenna to build and
play with.

Dan, locating the tuner at the feedpoint is certainly a method of reducing feedline loss. You will need very long arms or a remote automatic tuner. I have been surprised by how slow the market has been to match / excite the potential demand for a remote auto-tuner with balanced output (I think SGC does one, but I have no idea of how it performs).

Otherwise, the feedline is critically important in antenna system performance, and you can only determine that by analysing the entire system as a system.

>environmentally-unfriendly way to be a QRP operator.

Yes, but note that 20dB of feedline loss on 40m probably does not degrade the receive signal to noise ratio because even when external noise is decreased by 20dB, it still swamps the receivers internal noise, and signal to noise ratio is dominated by the (external) signal and external noise (both attenuated).

For example, if you look at Fig 2 at http://www.vk1od.net/fsm/FSAmbientNoise.htm you will see that expected ambient noise power in 2kHz bandwidth on 7MHz is somewhere in the range -87dBm to -108dBm, with somewhere above -103dBm (~S4) being typical in a good location. Attenuating noise at -103dBm by 20dB gives -123dBm, still way above the noise floor of modern receivers at about -135dBm. So from a rx perspective, it "works", demonstrated by copying other stations ok, just the S-meter reading is low.

One of our new Foundation Licencees asked me a question through a site feedback form some months age. It is relevant to this issue in a near QRP context, FLs are limited to 10W PEP on SSB, 3W carrier on other modes. Foundation Licencees qualify with about 6 hours of training, mostly on operational practice and very little technical content. The question and my response are below:

Question:

Why can't I get contacts on 80m. I don't have room for an 80m dipole, so I am using my 40m dipole that works just great on 40m. Of course, it would not be impedance matched on 80m, so I have used an ATU (which I was taught matches the antenna and line to the transmitter) and can easily get SWR of 1:1 (excellent match!). My antenna is fed with 25m of RG58C/U as an expert told me that it has a loss of only 0.6dB and I wouldn't notice that.

Answer:

It is true that the loss on 25m of RG58C/U on 80m under matched line conditions is about 0.6dB and for most purposes that might be quite acceptable. For reasons beyond your current understanding, your line is not matched, and the loss on your coax is much more than 0.6dB (about 15%), the losses are around 21dB (about 99.3%) and around 0.7% of your 10W output is reaching the antenna feed point. The good news is that the gain of your shortened antenna is still quite good, and your ERP (you learned about ERP for your licence) is probably around 0.1W (EIRP) broadside to your shortened dipole.

If for instance you were trying to work another station that is using a 100W transmitter and an antenna system efficiency of better than 75% (realistic), their ERP is probably around 120W (EIRP). To an independent observer who hears you both above the noise and has equally good propagation from both of you, your signal is 5 S-units lower than the other station. That disparity will make it very hard for you to work all but the very strongest of stations because of the ambient noise level, and even then they will be straining to hear you in the noise.

Your antenna efficiency will not as seriously impact your receive performance, because both the external noise and the desired signals are attenuated by the same amount, and are still well above the receiver's internal noise. The signal / noise ratio will be similar to using an efficient antenna, just the S-meter reading will be lower.

When you run less power than the other stations that you want to work, the performance of your antenna becomes even more important.

Owen

OCF, i think is the new term for something old. Nothing new in radio,
it just goes around in a circle and comes back with a new name.

Watch out for the G5RV it will come back as the tuner intergrated dipole
TID, since so many will forget what a G5RV is the TID will be a new
miracle antenna. I could be wrong here. They already selling antennas
with resistors in them, so who knows whats next.

I wonder when someone will release the light globe antenna for
restricted space. After all we know we can work DX with a dummy load.

I thought the mushroom principle was dead in ham radio, but some still
seem to believe that keeping you in the dark and feeding your BS is good
marketing practice.

> a "really" good price, would ensure it operated OK

After your comments, today I have bought the used ATAS-100 and, before buying, I have tested it.

I tried all bands, including WARC, from 7 to 50 MHz.

It has a good SWR on all bands except 7 MHz, where the residual SWR is too high for the FT-100D to deliver full power. With the manual procedure, I could determine that the antenna shows a clear resonance point on 7MHz, but at that point the SWR is not low enough.

However I still have to optimize the ground system in my car, so I hope the situation will improve on 7.

Thanks and 73

Gene, as you know, there is no such thing as a violation of
conservation of energy. But the reflectance at the thin-film
surface is 0.01 and a reflection is unavoidable. So how does
the reflected 0.01 watts/unit-area of irradiance keep from
violating the conservation of energy principle? Where does
that energy go? My follow-up answered those questions. Two
rearward pointing power flow vectors are associated with
wave cancellation of the EM fields. That's destructive
interference resulting in constructive interference in the
opposite direction.

801. Yagi Height Question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-14 13:32:21 UTC
From: CW <cpwendling@yahoo.com>
Message-ID: <1160832741.013618.210820@m7g2000cwm.googlegroups.com>
Source record: 51175

Fellows,

I've been wondering for some time now why amateur operators don't build their Yagi antenna's
so they can be raised and lowered about 10ft in addition to being rotated.
It seems to me that raising and lowering the height of a Yagi affects the take-off angle by at least several degrees, meaning that the signal delivery (target area) would be moved by at least many hundreds of miles.
It would also affect the average wave incidence angle with the ionosphere, so one could tune (or peak) the signal significantly with a few feet of height adjustment. I am aware of stacked Yagi's being used by some contest stations, where variable phasing feed techniques between the upper and lower Yagi can (and does) affect take-off angle.
I'm just suprised at how little literature and practical use of this technique exists. It can't be all that difficult to build a Yagi that can be winched, or slid up and down the side of the tower by several feet.
Does anyone have a better theoretical understanding of the possible signal strength change from an ideal one-bounce propagation when a 20m Yagi is varied in height from .9 to 1.0 wavelength in height?
How would a 0.1 wavelenght height change compare to a 30 degree rotation angle change?
I know that some of the difficulty in quantifying the benefits of such a scheme is that the refractive layers of the atmosphere change in altitude regularly. So take-off/refraction/range calculations become cumbersome. But perhaps some fixed assumptions would allow some general statements about the typical gains vs. antenna heights for a fixed range.

Thanks for any input on this apparently unusual technique.

[snip]

You make the all-too-common assumption that there is one "take off
angle" and apparently believe that no usable radiation occurs at any
other angle.

You wouldn't (I hope) believe that there is one azimuth angle and that
if your antenna isn't pointed *exactly* at the target you're SOL, so
why the concern about height?

Many do, using motor driven towers. In addition to lowering
their arrays when a storm hits, some raise and lower their
towers during marginal conditions to maximize signal strength.

its really only practical on crank up type towers, for those with guyed
towers its usually not possible.

10' change on 20m would likely not be very useful though. my hf stacks for
10/15/20 are all spaced 30' apart, 40m is spaced about 80'. even with those
height changes (which i can select instantly so i can make direct
comparisons without worrying about fading) there is often little difference
between antennas... though sometims there is a lot of difference. This
highlights the fact that often the signals arrive with a wide range of
angles, though at some times they must be in a relatively narrow range. so
having multiple antennas at different heights that can be selected in
various combinations is a handy thing to do.

Wes,

Of course I didn't assume that there is one "take off angle", but I did realize that there is a theoretical optimum take-off angle, and that the field strength diminishes as one moves away from that angle in a generally smooth and continuous way. This is obvious on any antenna radiation pattern chart. The point I was getting at was that the field strength diminishes in both the horizontal AND vertical planes. The common antenna rotator allows directing the radiated field in the horizontal plane, thereby "peaking" the signal in that plane.
There seems to be very little attention paid to peaking the signal in the vertical plane, which can be readily accomplished by raising and lowering the antenna height. I was curious as to the discrepency. The mechanical complexities just don't seem to fully account for the disparity in usage of these thechniques. I would estimate that rotators are at least 2 orders of magnitude more common than variable antenna height mechanisms. Since I'm assuming that both vertical and horizontal components of feild strength are important in HF signal propogation, I was wondering why so relatively little attention is paid to peaking the vertical component. Is it because of mechanical complexity, lack of understanding, or something else?

Dave,

Thanks for the reply. Multiple switched Yagi's at various heights is a
practical approach, and I'm delighted to hear that "sometimes there is
a lot of difference". What you are describing is a coarse grained
approach to the problem, which is also commonly done in the horizontal
plane by switching vertical antenna arrays, etc.
A fellow ham in the area has a Yagi mounted about half way up his guyed
tower, on a swing arm. It can rotate, but is limited to about 300
degrees of rotation. A similar setup could be used on a side mounted
tower trolly, where the height could be continuously varied by 30 feet
or more, AND rotated through about 300 degrees.
73,
CW-AI4MI

------------ REPLY FOLLOWS ------------

The answer is because it isn't really necessary in most cases. If you optimize your antenna for low-angle DX signals where you really need the gain, there will still be significant radiation at high angles, which are generally closer to you and will have stronger signals as a result anyway.

This might be significant enough for a QRP operator to want to do it, but at the 100 watt or higher level, you wouldn't gain much. Pun intended. :-)

Hi OM,

The single biggest factor is cost. You should be able to appreciate
the implication there.

The second (and related to cost) biggest factor would be wind load. A
taller tower is easier to push over.

Another factor would be the requirement for a very stout (cost again)
mast (more cost to lift more weight too); unless this is a telescoping
tower (costs more than a conventional one, doesn't it?).

About the cheapest consideration, the last one in this list, is what
you call "lack of understanding." The better question is:

What is the optimal angle for contact, not for launch?

Art recently came aboard here to seek validation for a secret design
that aimed "all" his power to England. When I did the modeling, that
optimal angle, depending upon
Frequency
Time of Day
Season
Sun spot cycle
varied from less than 6 degrees to as high as 12 degrees. FYI his
secret design is still secret.

Anyway, you can fulfill this last requirement (the cheapest) by using
two free software packages:
EZNEC for the launch characteristic of the NBS yagi vs. height;
VOAWIN (VOACAP VOAAREA) for propagation of that same antenna.

Uh huh. But I think there's an apples and oranges thing going on
here.

If you want to discuss antenna patterns v. height, that is one
discussion. If you want to discuss optimum propagation paths that is
another. "Theoretical optimum take-off angle" leaves me guessing but
I think you're referring to the former above and the latter below.

>The

>to peaking the vertical component. Is it because of mechanical
>complexity, lack of understanding, or something else?

I personally know at least a couple of dozen serious hf DXers
(presumably the more interested in "optimizing" this sort of thing)
and know of a lot more and I don't know of one of them that tries to
peak a signal by "readily" cranking a tower up and down.

But let's say it's easy to have a free-standing, 100' high (the limit
in my county), motorized, positive pulldown, crank-up tower that we
are absolutely confident we can crank up and down while out of sight,
without worry of the coax getting jammed up or the winch cable wearing
out, etc.

Atop this tower we install a well-designed, 3-element, 20-meter Yagi.
The ground is unremarkably average.

Suppose that despite all of the propagation vagaries there is a DX station we want to work and the "optimum takeoff angle" to his location is 13 degrees.

Let's begin with our antenna at 50' above ground.

Using EZNEC, I modeled such an antenna (my design) and find that at 50' above ground, the gain (13 dBi) peaks at an elevation angle of 18 degrees; not "optimum" for this path, so we start cranking.

At 75' the gain (13.4 dBi) peaks at 13 degrees but we don't know that so we keep cranking until we reach 100'. At 100' the peak gain (13.6 dBi) occurs at 10 degrees; again not "optimum."

At the "optimum" 13 degrees, the penalty for having the antenna at 50' is 0.9 dB and for having it at 100' is 1.2 dB. Now the question has to be, can you tell the difference?

(The math is correct BTW. Elevation patterns are not symmetrical)

After all of these heroics, for all practical purposes, we can't tell the difference, but if we are wrong, we're better off at the *lower* height.

Maybe this is why nobody varies their antenna height to peak the signal.

811. Radials -- the same length or not???

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-14 21:18:07 UTC
From: Hank Zoeller <bogusaddress@dontbothernotvalid.com>
Message-ID: <453154e3$0$1717$c3e8da3@news.astraweb.com>
Source record: 51035

I'm constructing a vertical antenna and I'm about to start laying radials.

F/O will be 40 through 15 meters. The vertical element will be 26 feet in height. There will be a remote controlled antenna coupler mounted at the base. I'm using 18 AWG magnet wire for the radials. The radials will be short (no options here) but there will be a lot of them. I plan on about 18" of separation between the radial tips and I have more than enough radial wire to work with. The radials will be stapled directly to the outer surface of the planet.

I could cut the radials to be the same length, forming a circular pattern on the ground. Or, I could vary the lengths to take advantage of the available land, which would result in a square pattern on the ground. In either case, the antenna would be in the center of the radial field. And, in either case, opposing radials would be of the same length.

The square radial field would allow some of the radials to be longer which seems desireable. The circular radial field would be, well, circular..

The circular pattern radials would be about 25' long. The longest of the square pattern radials would be something like 35' long. (Assuming my high school geometry isn't as hazy as everything else from that long ago era...)

The radials are laying on the ground, and non-resonant, does it matter if they're all the same length? Is the symmetry important? If I go with a square pattern how careful must I be with the radial lengths? Is this a measurement to be made with the hairy eyeball or do I need to get out measuring tools?

I'm inclined to just cover the available ground with as much copper as I can and call it a day. This would result in a square-ish pattern on the ground with opposing radials being similar in length. Is this inclination fraught with peril?

Or hows about raising and lowering the angle of the Yagi? Tilting it
somewhat? Maybe a winch and cable to the end of the Yagi and some
kind of rotatable joint at the tower end. That would also be complex
and cost some.

Tony

It is more a question of practicality.
It is being done by those with crankup towers, if they want to optimize, say between DXing at low angles and domestic QSOs at higher angles. If you want to be flexible, get crankup tower and StepIR antenna.

What you suggesting is asking for mechanical complexity, guy wires, multiple antennas on the same tower in the way, etc.

Propagation is not clear cut X angle. It is more like drunken, wobbly signals varying in angles, polarization and direction. Antennas have quite a wide lobes to accommodate most of that. Serious DXers and contesters use stacks that give them instantaneous selection of major angles.

Tilting up antenna about 5 deg. helps somewhat, beyond that it doesn't. Vertical angle of beam is given by the height of the antenna.

So it the question of practicality vs. "precision" and complexity. Moving it 10 ft up or down doesn't really buy you anything.

Hank,

My understanding of a radial system is it is basically a very conductive ground. Not so much a counterpoise - you try and make the earth the counterpoise. Nonetheless, the ground will detune your radials. So, no matter what length the radial, you have no way of predicting it's resonate frequency. That will be determined by soil composition and moisture level, etc. And it will vary from day to day.

I'm not sure, and some one else should chime in, but I am almost certain that your radials should not be insulated from the ground. Magnet wire is normally varnished and therefore insulated. Given your plan, chicken wire would be better, and the cash value of the copper would more than pay for it.

Electric fence wire is aluminum, comes on 1/4 mile, 1/2 mile and mile rolls, works great for ground radials but is to soft for antennas, IMHO.

Best wire I have found for antennas is what the local phone co-op calls "field wire". They lay it down during the winter when they can not trench in a new copper line. In the spring they roll it up and toss it away after they trench in the new line. This stuff is 7 strands of steel, covered with a UV protective outer plastic shell. Stuff will last for years, stretch and return to shape, and if you bundle enough together you can pull a car out of the ditch in a pinch. Have had it up for years as a 40 and 80 meter dipole. Hard as the dickens to work with, almost impossible to solder, but, it makes a dipole even northeast Montana winters can not break, something to be said for that.

Just my two cents worth.

Sam

Simple rule for (non resonant) radials in or on the ground:
1. Mo' - da better
2. Longer the better.
3. Better to use (insulated) wire on the surface than buried. Just stretch it out and let the grass grow over.
4. Water before contest or major DX hunting.
5. Forget the above and set it up on the salty beach.

"note that 20dB of feedline loss on 40m probably does not
degrade the receive signal to noise ratio because even when external
noise is decreased by 20dB, it still swamps the receivers internal
noise, and signal to noise ratio is dominated by the (external) signal
and external noise (both attenuated). "

Yeah. This is the counter-argument to "if you can hear 'em you can
work 'em"

Mismatched line loss needs to be covered on the entry level tests.
Heck, I think they should give it two questions. It's a major issue in
setting up your first station because all the tuners have two or three
SO-239 jacks and one "random wire/balanced line" output. Same with the
radio, tuner inside, coax connection outside. Who knows better than
the engineers that built the stuff, you know?

Well, I don't know if I've converted anyone yet but I often point
people to this page:

http://www.n3ox.net/projects/servo

It's the electromechanical equivalent of having long arms, and it's
ALMOST cheap.. I hope to inspire a few folks who've dropped a bunch of
money on a nice tuner before they discovered the tuner-at-the-feedpoint
advantage, though there are a couple of snags to work out before it's a
tuner add-on that anyone can build. I need to figure out something
better than 10 turn pots because they're hard to get and kind of
pricey, and MFJ, who seems to sell all of the budget tuners, has
stopped selling switched-inductor high power tuners. You can still get
them in the "300W" class, but no more of the "1500W" ones.

I'm not even using the remote tuner at the moment. I've rolled my own
fixed L networks for matching my 20m delta loop on 20 and 17 and my 40
foot vertical on 80,60,40, and 30. The remote tuner served me well for
the apartment doublet but I like the faster bandswitching with the
switched networks. I thought about making fixed, switched networks for
the wire I had up at the apartment, but it was 30 gauge wire and broke
too often, and I couldn't really control the exact length of wire I was
putting up every time, so the tuner really was a better solution. I do
a lot of band hopping while I'm on the air (DXing, mostly) so retuning
all the time was something I wanted to avoid in the new installation.

That actually changes it a lot less than raising and lowering
significantly. HF yagis a wavelength or two above ground don't have
laser-like beams. The elevation pattern is set up substantially by
ground reflection, not only the antenna's free-space elevation pattern.

Check out

http://n3ox.net/pictures/20m_yagi_el.jpg

for an illustration of what happens when you tilt a 5 element 20m yagi
up toward the sky. I don't remember how high it is; I think it's about
1 wavelength high. The traces are for 0, 20, 40 and 60 degrees
inclination.

73,
Dan

So, once again, I give in to temptation. I feed a troll. I admit, this is a particularly hideous troll, what with all that black hatred oozing out of every orifice, but I cannot resist.

My dear troll, gay people are, on the whole, honest, above-board, decent people, who'd never even, in their wildest nightmares, molest kids. Yes, there are exceptions, but they are in PRECISELY the same proportions as the similar exceptions in the straight community.

There are the same percentage of pedophiles in both groups!!!!!

The assumption that gays are pedophiles reveals both your rank bigotry and your pathetic ignorance.

You are beneath contempt. Go flush your head.

Leanna

Here's a reality check.

On 80m the rest of the world, except Canada, has always had phone down to 3600 as far back as I can remember, and we are merely joining them. The VE phone ops still have to stay above 3700, I think.

On 40m the international bandplans have phone down to 7040 except in Region 3 where it is 7030. The only countries that I know of where you can't use phone down to 7040 are Mexico (7050) and the USA (now 7125 after the change).

US hams outside Region 2 have had phone down to 7075 for years, and I am on record as suggesting that we should have that in the mainland US. It's hard to see why not when you actually look at what the rest of the world is doing.

At the same time countries in Region 1 aren't supposed to get access to 7100-7200 until the middle of 2007. Many of them already have, but for those that haven't, a phone subband that goes down to 7125 still doesn't even reach the top edge of their whole band. Doubtless some of them will be late in implementing the extra spectrum, so forced split working will drag on a while longer. How would you like it if your 40m CW allocation were on frequencies that were off limits to the DX?

On 20m and 15m we still have 50 kHz less phone on each band than all other countries. Although General and Advanced got bigger phone subbands on 15 (as well as 80 and 40), the bottom edge of phone didn't move on 15 (or 20).

Cecil
That makes a lot of sense after all if one has the antenna primed for low angles then propagation will render it useless as time goes by for those particular angles. If by tipping or feeding another element in an array you can move or thicken the main lobe you can increase the gain of a signal by more than 2 S units then it is certainly worthwhile.To view the subject purely around the maximum gain angle of the main lobe is fallacious as it is the signal that falls just outside the main lobe contour that may be the most desirable and subject to the largest possible gain with the smallest change of TOA. This is because the main lobe thickens out to cover the deep crevice of non coverage of an array tuned for a low TOA.and allows you to emulate the performance of a stacked array with the use of the lower beam alone. 2S unit increase of a signal that can be barely heard is much more advantageous than increasing the gain of a signal that is blowing away all other nearby signals, it certainly allows for more communication data to be transferred where initially very little could be heard.
If a good contact is underway it is certainly desirable to maintain that contact even tho propagation is changing and that is what the original poster is seeking

Alun,

With all due respect, your signature line kind of reveals your agenda. We aren't talking about Extra's who don't use CW/rtty/data. The folks we're talking about here are Generals, the most populous HF license class in the US. On 75m they have just had their CW/rtty/data spectrum reduced by 2/3rds. That's outrageous!

---------- REPLY FOLLOWS ----------

Not necessarily worthwhile. Remember, if your antenna is optimized for low-angle weak DX signals, the high-angle signals are going to be much closer in and therefore much stronger to begin with. If you lose a few dB on a S-9 signal, it won't matter.

If this was really a good idea, everybody would already be doing it. As I mentioned before, it might be desirable for someone running QRP or micropower, but not for most of us at the 100 watt or greater level. Spend your money on other things.

Bill, W6WRT

That' may be true in theory, but not in practice. You can't use CW on frequencies which your license class prohibits. Generals just lost 150kHz of prime CW/rtty/data spectrum from 3.6 to 3.75MHz, the other parts of the band their license class doesn't allow. So much for "CW everywhere in band".

No, the rules concerning CW use have not changed. Those rules have never allowed a General to transmit CW (or anything else) in frequencies reserved for Extra and Advanced. In the case we're discussing the 150kHz from 3600 to 3750 have now been reserved for Extra and Advanced, and are now off limits to General who previously could transmit CW/rtty/data in that segment.

hmm they lost acutals hz did they? is that what you are tlaking around
or did things just get shuffed around same number hz justchanging the
mode avalable

in the later I say where the beef if they lose acutaul hz for any use
(total number for all modes then I have to wonder

Keep in mind that the US has more hams than the entire rest of the world combined if you don't include Japan in that count. So there is the potential for problems if our voice allocations go too low. Our regulations need to take that into account. As far as 40m goes, it will be a better solution if they can move the broadcasters out and make it a worldwide ham allocation up to 7.300. If the rest of the world could go to 7.3, that would open up a tremendous amount of space for other countries.

The comment is that you can use CW anywhere within the allowable
frequencies for you class of license.

I personally would like to see all amateur frequencies
open to CW operation by any and all classes of licenses.
Want an incentive? There it is.

Anyone ever heard of a finco stinger A2+2 yagi 2M beam?

If so where can I find a manual on it?

Thanks

If a incoming signal aligns with the null between lobes then the
receiving station is deaf to your signal. Moving the lobe slightly
upwards can add a few db as you call it and allow for communication. If
you yell at a closed door you do not increase communication, whisper
under the door and you can then be heard, Its all relative. As far as
those that follow lemmings do it all the time.

If you do a Google search you will find entries for a Finco Stinger CB antenna but not a 2M beam.

Since 1955 for international civil aviation. It's taken
from the NATO approved phonetic alphabet which came out
earlier the same year. I remember it well since I had to
learn the "new" phonetic alphabet in a hurry while in the
Army then. :-)

>> When things start failing communication wise worldwide, amateur radio
>> might be all there is to relay messages, and the ITU just removed one of
>> the legs of a three leg stool.
>
>Dear Slow, air traffic controllers don't use Morris Code, and they
>communicate with foreign speakers JUST FINE!

Ever since 1955 the worldwide common language for civil
aviation communications on airways has been English
spoken as well as (now) data. That includes pilots as
well as controllers, even in and over their native
country; a non-English speaking country MAY use their
native language but the civil airways can have many
nations' aircraft in it.

Blowcode is just another troll who has his head up his
ass in regards to radio communications. That head just
hasn't been aware of what happened in radio for a half
century.

The ITU didn't "just remove" anything. The ITU-R made
the code test for an amateur license with below-30-MHz
privileges OPTIONAL to each administration. In 2003.
THREE years ago, not "just now." :-)

This needed to be down years ago. Good to see the ARRL and the FCC are listening to the active Amateurs and doing what the majority want.

Interesting to know that Phone operators are appliance operators and CW operators are not. I guess the CW operators are all using Homebrew equipment and if not then I hope at least that every one of them that own a Yaesu FT-1000MP / D have done the CW modification and did it them selves without senting it to a repair place ?

Alun you've been dumping this old whine into the groups for years now
and it's long since worn out. Not that it needs to be explained to you
again but the FCC is *protecting* the dx from the hordes of Yanks who
would obliterate the dx if we were allowed to run SSB below 7100.

Dee also explaned it in her immediately preceeding post, read it, give
us a break and internalize it this time then go find something new to
grouse about for the next five years. Maybe by then your chums in the
UK will be able to transceive with you above 7125.

> How would you like it if your 40m CW allocation were on
> frequencies that were off limits to the DX?

The difference is all about one SSB signal taking up the same amout of
spectrum space as 5-10 CW signals.

Source record: 51079

my stacks are all monobanders.
on 40m its 4-ele's at 180' & 100'
on 20m i have 4-ele's at 150/120/90/60'
on 15m and 10m its 4-ele's at 120/90/60/30'
on 20m, 15m, and 10m there is another 4 ele fixed south.
also on 20m, 15m, and 10m, the middle 2 are fixed at europe and selected
together, and the bottom ones are on ring rotors and separately rotatable
from the top one.

so on 20m, 15m, and 10m, i can select the top along, the middle two at
europe together, the bottom one alone, or the south one alone. And then i
can also select the top, middle, and bottom all together, and the top,
south, and bottom all together to spread the signal out when the bands are
open in more than one direction.

I still have and use a Finco 6 and 2 meter beam. I haven't seen an ad
from them in a ham magazine in many years. I don't know what they may
have made for just 2M.

Finco, if memory serves was a manufacturer of
antennas, back in the dark ages, around 50 years
ago, and , NOT the sharpest tools in the shed!
They work, BUT forget gain claims, and directivity
claims. For local work, they be ok, BUT for DX,
FORGET IT! (unless you are extremely luck to catch
a band opening on 2 meters) Remember articles on
how to improve Fincos, on 2 (and 6 meters), but
those would even be suspect in this day of
antenna modeling programs!-- Jim NN7K

Hi Cecil,

The FCC R&O does NOT indicate any change in CW frequencies--it only gives more spectrum to phone operation. Hans needs to take Reading 101.

Depends what you want. Are you going to use a small Yagi for FM work or
a long boom Yagi for SSB/CW? If you want something fairly simple, a
homemade 6 or 8 element Yagi is fairly simple. Otherwise, for some
serious weak signal work, the K1FO designs are quite commonly used.
Directive Systems sell them... http://www.directivesystems.com/antenna4.htm

Hope that helps!

Hi Walt, I believe Hans objection is that if 3600-3750 is
awarded exclusively to Extras then Generals will not be able
to operate CW there anymore even though CW is still allowed.

Are you an Internet only type of person?

The original design was perfected by Steve Powlishen, K1FO, who spent hundreds of hours optimizing yagi designs on a high powered Hewlett Packard computer.
He started with some computer optimized designs of Tom Kirby, W1EJ, (SK) who was using computer software developed at Ohio State University. W1EJ had came up with many excellent VHF long yagi designs.

The finished K1FO designs were carefully checked out in the real world by K1FO to ensure accuracy of the design effort. His efforts have produced an exceptional design with maximum gain very close to the maximum amount possible, while keeping side lobes, (particularly those of the H-plane) at a very low level. The net result is broad bandwidth, wide beamwidth, and clean lobe structure.
Clean H-plane patterns translate to efficient stacking with maximum possible gain and manageable array side lobes.

The design has been published in MANY printings of the ARRL Handbook.

Now you tell me. I just ordered 2 beams from M-Square, one for 432 and one for 144. Wish I had the K1FO antennas as I had one for 432 and it worked very well. I did not know anyone had picked up the K1FO design after he became a SK.

Now now Tony, be carefull in what you say and how you say it

If you placed several dipoles above each other in an array, say nine of
them within a height change of half a wave length, in line and each of
the dipoles/elements were resonant at the same frequency you are then
infering ......,at least I think you are,..... that the lowest
dipole/element will have the highest TOA, the next element in height
will have a lower TOA and progressively until one energises the top
element to get the lowest TOA of them all..... If that is what
you are saying..... then you could not be more wrong.
I am sure that those who are really knoweledgable in the field will
agree with me.
Ofcourse somebody lacking true knoweledge will produce a fake series of
radiation patterns for each element in the array but that is par for
the course on this newsgroup.
But then again often interpretations can be varied and thus in error if
so I apologise.
Best Regards
Art

Hi John,

The coupler is a Harris RF-601.

I suspect the Harris would match this antenna on 80 and maybe even 160
but I have no illusions about getting much radiation out of it on those
bands. My intention is to use in from 40 through 15 meters.

How tall is your antenna going to be? I'd enjoy having an 80 foot
vertical for 160 through 40 but that's just not going to happen. I'm
looking for low visual impact here..

Hi Jim,

I'm pretty convinced that magnet wire on the surface is the way to go.
The RF won't have to go through lossy dirt on it's way to the radials
and they'll last for a long time. Chicken wire would rust up pretty fast..

Besides, the magnet wire was nearly free!

I don't know if this helps, but advice for TV DX says that you get
progressively improved performance until the yagi's
height-above-average-terrain (HAAT) is equal to about ten wavelengths.
(Above that HAAT, the signal strength varies up and down with further
increases in the elevation)

I never tested the idea, but if correct and it also holds for HF, there
won't ever be anybody _lowering_ a HF yagi. We would want the most height.
At the 2006 Field Day, one team had multi-band beam at 85 feet and everybody
loved it.

Before anybody tells me there is a difference between a yagi and a beam, let
me thank you in advance. I cannot formulate a sensible distinction
between them and I welcome the knowledge. I presume the terms are related
but not interchangeable.

David that is quite an array of antennas. Two questions come to mind.
Why the separation of a half versus 0.6 of a wave length?
and 2 do you ground the top antenna when it is not in use or let it
float?
I have heard that the top array can remove static noise to advantage
and I was wondering how that would compare to an elevated mast that
would provide a cone of protection and thus allow use of the top array
regardless of conditions.
Regards
Art

Yes there is a difference, A yagi is a planar beam ie on a single plane
so the height of the array is the same for all elements in the array
which creates a major lobe or beam.
If the array is not planar such as a Quad then the elements are at
different heights
so the true or effective height of a quad antenna which is also a beam
style antenna is approximately the center point of the array or
somewhere between the top and bottom of the quad element.
The point to stand by is that the height of the feed point is
immaterial with respect to the effective height of an array. In another
post I pointed out that no matter which element is fed in a array the
effective height of the array is always the same and thus the TOA is
always the same

>became a SK.

Important correction: Steve Powlishen, K1FO, is NOT an SK! (W9GB had it correct: the person who died was the co-developer W1EJ.)

W9GB is also correct that they are excellent yagis, and have been published in several editions of the ARRL Handbook. The most extensive write-up is in the ARRL Microwave Experimenter's Handbook Volume 1.

Don't worry, you'll be fine with an M2 yagi as well. There is a lot of convergence between modern long yagi designs, so the state-of-the-art is that products from all the major manufacturers are very close to optimum performance in terms of gain and pattern.

There can still be some differences in performance between different brands, depending mostly on the exact balance between gain, pattern and bandwidth the designer was trying to achieve. However, these differences between brands are almost always quite small, so for comparable designs (ie yagis with the same or very similar boom length, of 2-3 wavelengths or more) the difference between brands might only be a few tenths of a dB in terms of gain, and maybe a few dB difference in the levels of minor sidelobes.

End users will hardly ever notice these differences on the air, so when choosing which long yagi to buy, you can pay more attention to other important factors, such as overall size, style of construction, suitability for your weather conditions, price and dependable product

support.

[I could write a lot more about "optimized" long yagis, but not this morning. There's more information in the 'Long Yagi Workshop' section of my website.]

Source record: 51108

If you don't mind having a little less gain than is ultimately possible
by using an antenna modeling program, the NBS (Nation Bureau of
Standards) designs are pretty straight-forward. For a 6 element Yagi,
here is element lengths and spacings for building with insulated
elements (insulated from the boom, so I would use wood, 1" X 2" X 8.5')

Lengths:
Reflector = 3' 4"
Driven = 3' 2-3/16"
Dir 1 = 3' 7/8"
Dir 2 = 3' 7/16"
Dir 3 = 3' 7/16"
Dir 4 = 3' 7/8"

Spacing:
Ref to Driven = (187.2/Fc) X 12
Spacing between all other elements = (234/Fc) X 12
where Fc is the design center frequency in MHz, ie 146 for the center of
the FM portion). The spacing calculations give the answer in inches.

Then you need to feed it. I use delta matches. Are you good at
qrz.com? If so I can send you a drawing of the feed to get you started
(but you would need an SWR meter that works at 2M to get it adjusted).

How about 60 feet?

http://www.spiderbeam.net/sb/images/product_images/info_images/18m_pole/08_18mpole.jpg

My approach, since it's a low band antenna, is to put the black
fiberglass pole at night, goes up just before dusk and down in the
morning... I have the 40 foot version.. I don't know if you're
looking for stealth or just low-profile. I'm not antenna restricted or
anything, but I don't see any reason to make my neighbors look at the
vertical all the time.

Probably CushCraft. There are so many of these around that they are also not
hard to find used at hamfests. I once picked up a 7 element for $8. Can't
buy the aluminum for that. A friend of mine used 4 of their Boomer models
for moon bounce. Only thing I don't like about them is the gamma match.

Those darned new hams. They never should have been licensured in the
first place. Didn't have the ooomph to get licensed when the tests
were harder so they weren't really that innerested in the first place.
Didn't show the proper dedication.

>looking for low visual impact here..
I started with a 28 foot radiator and 3 radials. The focus has been on
the radiator, not the radial system. It has been easy to deal with in
both modeling and testing on 40M. The 40M (at 50') dipole included in
my A3S beam does seem to outperform it. That may simply be due to the
lower angle radiation of the vertical. On 80M the 28' vertical does
not seem worth much compared to a dipole at 45 feet. And the dipole is
resonant and well behaved.

At 160 meters it is tough to feed. Or may be impossible from my
perspective. It models OK, but matching schemes seem to be awkward and
inefficient. My latest idea is to use a vertical wire from the base of
my tower and bend it over at the 45 foot point and then horizontal to
a tree. If it models well, I will put it up and test it. I live in the
country and have several acres to work with.

Hi Art,

One of the most demeaning aspects of this newsgroups concerns misunderstandings of definitions and terminology that often leasd to unfortunate and unnecessary arguments.

To wit: Yagi vs beam.

It's been my understanding that any combination of radiating elements intended to radiate more energy in one direction than omni establishes a major lobe that is called a beam. In other words, any directional system establishes a beam. Therefore, 'beam' is generic to all directional radiators.
It then follows that 'Yagi', 'quad', 'W8JK', 'EDZ', are all 'beams' of a particular type or configuration.

I believe it's important that correct terminology be used for the benefit of the newcomers--would you not agree?

900. Re: 20 M vertical ground plane antenna performance?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-16 19:34:01 UTC
From: Wimpie <wimtel@tetech.nl>
Message-ID: <1161027241.377203.145680@i42g2000cwa.googlegroups.com>
Source record: 51124

Hello Steve

About 20m band antenna height.

The height of your antenna depends on what you want to do.

For "local" daily traffic (ground wave propagation [not confusing surface wave propagation]) you want as much as possible signal strength in the horizontal plane (low elevation). In that case height gives stronger signal. No matter the polarization, over land (for very small elevation angles) the ground reflected wave is opposite to the direct wave (elevation << (pseudo) Brewster Angle). More height gives some more phase difference between direct ray and the ray that arrives after ground reflection. The "two ray propagation model" is based on the direct wave and ground reflected wave (for very small elevation). So the CB people aren't that crazy.

When the height equals many wavelengths, you get many lobes in the elevation radiation pattern, but for local traffic this is not important.

For sky wave propagation the situation is different (as also mentioned by Greg). If you don't want lobes in the elevation radiation pattern, your height is limited to about halve a wavelength. Further raising the antenna gives lobes, but the elevation of the first lobe decreases.

About losses. You have near field and far field losses. If you place your antenna about a wavelength (or more) above ground, you have far field loss only. However placing your quarter wave with some radials close to ground will bring the ground within the (strong) reactive field zone. This increases the ground loss (you will notice this by an increase in the real part of the input impedance). You can reduce the near field at the ground by adding more radials (as suggested indirectly by Greg).

In my previous posting I suggested to higher the base of the antenna. This is also to reduce ground losses. A quarter wave vertical has low input impedance, causing relative high current in the radials. When the radials are close to (or in) the ground, losses do occur.

I did some simulation on a quarter wave vertical (20m band) fed over 4 radials (horizontal), placed at various heights above ground (15m thick dielectric layer representing average ground, very long run times, IE3D 3D planar simulator). The results were bad (Radiation efficiencies below 10%). More height gives lower ground dissipation. I hoped to get better results with a halve wave radiator (high impedance, hence reducing the current in the radials significantly). The simulation

showed a significant increase in radiation efficiency (above 54%).

A halve wave radiator with 4 horizontal quarter wave radials (radials 2 m above average ground) has a first lobe at 17 degrees and about 4 dBi in that direction).

So steve, I would recommend you to extend (if possible) the radiator to a halve wave (you need impedance match at the base), you can run your radials in the horizontal plane, radials should not touch ground. Extending a 5/8 wave does decrease the input impedance (hence increasing the currents in the radials) and thereby increasing the ground loss.

If you cannot extend the radiator, then increase the base significantly so that the ends of the radials are several meters above ground, and / or use more radials.

I hope this will not give confusion.

Best regards,

Wim
PA3DJS

Walt
I said that both antennas are beams. What I was addressing was the
height portion of the question whereas tho they are both beams the
effective height measurements were different.
i.e Planar beam versus other beams where the quad is not a planar beam.
Seems like effective height measurements contribute to most yagi /quad
comparison debates. There is also another side of the coin when
measuring effective ht and that is when a yagi is positioned vertically
where it is still planar when comparing to a quad element moved thru 90
degrees.which is now planar. If you chose to answer the posting what
part of my posting would you leave out, or question its veracity
especially after reading the total thread?
Regards
Art

XXXXXXXXXXXXXXXXXXXXXXXXXX
I agree, where did I say different?
XXXXXXXXXXXXXXXXXXXXXXXXXX
>
> I believe it's important that correct terminology be used for the benefit of the
> newcomers--would you not agree?

Yes I would agree but if one is unsure of the true terminology should
we ban all from ham radio as it has now moved from a hobby to.......
IEEE transactions on antennas ?
I believe everyone has become too picky as to who is a ham and who is
not and thus are becoming adverserial to those not fully versed in the
art. Look at the long posting regarding
antenna efficiency where everybody jumped on the electrical version of
efficiency ie transfer of electrical energy to a time variant field and
totaly ignoring the reference to pattern volume.with respect to the
main lobe portion. How on earth do electrical engineers chose
iapliances for the home when so much device energy is wasted or does
not imprint on the required use?
The majority of people on this newsgroup including newcomers are now
convinced that energy entering an array is nearly equal to the
radiation energy contained in the single main lobe and they contest
other thoughts by the use of " ratios": which is devoid of units and
relavence. Even if they didn't want to read the posting as a whole not
one looked at radiation efficiency change when viewing radiation from a
complex circuitry direction or in other words driven elements in
parallel since elements in parallel alter the resistance DC to
resistance radiation ratio ,admittedly small but there none the less. I
would admit to a review of antenna efficiency or radiator efficiency if
it was normal for radiators to be made of wood As I said earlier to
much nittpicking going on such that hams are becoming adverserial to
each other and that is to bad if we want newcomers to stay around.NUFF

It's telescoping friction fit fiberglass like those fiberglass fishing
poles everyone's using for portable antennas, just much heavier duty.
I just guyed the bottom section of mine (40 inches up) with a few tent
stakes and that's enough to support it in a breeze at least. I'd make
a good base support of some kind if you'd leave it up in the wind, but
I don't. If the WX is bad I take it down. We'll have to see about the
winter, I might want to keep it up in bad winter weather... bad summer
weather always means thunderstorms, and therefore, QRT!

Ok Art, here's the way I saw it:

Sal Manela sez: "Before anybody tells me there is a difference between a yagi
and a beam, let me thank you in advance."

Then you replied, "Yes there is a difference,"

So Art, my response was only to refute your statement above. I don't dispute
your other statements.

Walt, W2DU

912. NEC and computer speed

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-16 22:43:35 UTC
From: W1HBQ <anderross@gmail.com>
Message-ID: <1161038615.902202.311240@m7g2000cwm.googlegroups.com>
Source record: 50986

I'm planning to buy a new computer, and its main task will be for antenna simulations using NEC. The issues appear to be: Intel verses AMD, single verses dual core, front side bus and RAM speed, and of course processor speed. I would appreciate any guidance.

It would be interesting to compare computation speeds of various computers for the same antenna. One possible antenna to use for comparison is The Grid Yagi from my website:
http://home.comcast.net/~ross_anderson/GridYagi.htm
http://home.comcast.net/~ross_anderson/GridYagiD1.htm
My three year old Dell with a Pentium 4 2.8GHz with HT and 3GB DDR of RAM at 400MHz using the Nec2dXS*.exe calculating machine gives:
- - - MATRIX TIMING - - -FILL= 12.469 SEC., FACTOR= 11.422 SEC.
I'm interested to see how this compares to more modern computers.

that separation comes about from the spacing of guy wires on the rohn towers
they are on. it also happens to work out reasonably well with the elevation
pattern software since that many antennas fairly well covers the whole range
of take off angles from new england to most of the world.

all my yagis are completely grounded designs anyway, so there is no need to
further ground them when not in use. when there is rain or snow static the
top one often becomes too noisy to use while lower ones are just fine...
another good reason to rotate the bottom antennas (except on 40m where it
won't turn under the guy wires).

> everybody
> loved it.

no, it doesn't hold for hf. tv dx is basically a line of sight vhf/uhf type of propagation where height is everything. the higher you can go the better, i don't know where 10 wavelengths came from since that is actually pretty low on the higher uhf channels! on hf you can't get high enough to get away from the ground reflection effects so you might as well put them to good use. And yes, when bands like 10/15/20m are wide open from new england to europe the best antennas are often the lowest ones here... i.e. my yagi at 30' on 10m will have much stronger signals than the ones at 60, 90, or 120'. and yet at other times, like now, on 10m my yagi at 180' is often the only one to hear any dx.

so the answer is: yes, you can be too high, but no, you can't get too high.

Hi Ross,

Can't say much for computer speed, but the antenna is interesting. It
is certainly resource hungry to model and I can see why you want
speed.

Big mistake on my part. I was thinking of Rutland Arrays. The owner of
that company (small one man shop mostly) is the one that is a SK. He sold
the K1FO type antennas. He used to show up at the Shelby, NC hamfest and
that is where I bought the 432 antenna about 10 years ago . I really liked
the way it was made and it seemed to work very well. I have a handbook or
two that have the K1FO designs in them. Just don't have time or equipment
to put one together.

I may be wrong, but was thinking the M2 antennas were based on the K1FO
designs also. That was my reason for going with them.

It friggen figures the president of the ARRL would say that. They're only interested in selling memberships, they're not interested in the quality of the radio amateur. Ham radio can be like CB for all they care.

I'm not against choice. They can choose to be a ham, or they can choose
to be a CB'er. What they have to decide is how bad do they want to be a
ham. I enjoy hams on the bands, if I didn't, I'd buy a CB.

That's what happens when something gets dumbed down. It cheapens it, and
people find no value in maintaining or continuing with it.

He's upset because he knows CW helps makes a real communicator, and he can't cut it. That's OK, I encouraged him to try to learn CW while I could before I ended up in the killfile.

Anyone that made or is making an effort to be able to copy CW at 20 WPM, isn't going to have a problem having fun releasing a little solder smoke building things. The old 20 wpm extras seem to me to get more out of being a radio amateur than these latter day no-codes and nickle hams. Maybe that is why we see people getting licensed and they leave the service before their license even expires.

Getting a license and then leaving, that's not how it should be.

No, You missed another ten questions, the CW questions, but since the
Tech license is dumbed down you weren't tested on them.

Don't know which HT to recommend, but a lot of No-codes like the
Cobra 148GTL for HF.

ARRL is willing to let the problem get worse by not supporting policy that
will improve or at least maintain the quality of individuals getting
licensed. Maybe they don't care if hams are like CB'ers as long as the
memberships keep rolling in.

Can you say: Breaker Breaker 19? That's where we're headed.

It's started going down hill about the mid-eighties and the ARRL pushed to
make it go down hill faster. That crash at the bottom ain't gonna look
pretty... or sound pretty.

> No, You missed another ten questions,

No I didn't take the code test. You're absolutely no help. You just
try and stir the pot. If you have so much knowledge why don't you share
it with the group instead of just causing trouble.

> the CW questions, but since the
> Tech license is dumbed down you weren't tested on them.

I took the test the government of my country prescribed I take. If you
don't like it call the FCC. I've long since tired of your whining.
>
> Don't know which HT to recommend,

I thought you knew everything there is to know about Ham radio. I
thought you were the upmost authority on everything.

> but a lot of No-codes like the
> Cobra 148GTL for HF.

Sounds like you know from experience. Now we know who the CB expert is
on the group.

What? Haven't got a buck?
Check out www.TeslaRadio.org
we got some 200 acres of salty marshy QTH with two story building and 40 rhombics for a $1. We are looking for extra hands and brains to help with restoration and operating.
I just put some more pictures and partial drawing of antenna farm (under location -maps - site survey).

Hello Yuri,

Just checked out the Tesla site--veerrry impressive! And congratulations on founding the Tesla Radio Foundation--Bravo! Tesla was indeed a great contributor to our art and science, and I agree that he has not had the recognition he deserved. You are performing a splendid service.

And what a great site for a ham station--the old WOO station! Hope you can put those rhombics back in operation. I've just committed one of the seven deadly sins--I'm green with envy!

Walt W2DU

Just got a note in the mail for license info
Why are they asking for my social security number?
Have they got a shortage to dish out to illegal immigrants
or is this only required for those who are providing a service for
money?
I really dislike the idea of giving out this personal information to
non
government employees. Also why are they asking for tel numbers
and E mail addreses are they selling these lists to businesses for
money?
Am I going to now be flooded with solicitations from businesses to the

same level I get charity requests.
Note that they are also taking down
credit card numbers to make it easy for identity theft
I am beginning to think that what I have got in the mail is
a scam and not a wise thing to fill out
as I have no idea as to the security of the information. and to
who really sent it to me . Could be another PAYPAL scam !

Yes, this has been my experience -- I need to get higher than my neighbor's
roof, for example.

> i don't know where 10 wavelengths came from since that is actually
> pretty low on the higher uhf channels!

Another Yes. At 600 MHz (near mid-band for UHF TV) 10 wavelengths is a mere
5 meters. Not much of a skyhook required to get up there!

Doubtful this applies to HF skywaves. Thanks to all..

Hi Walt,

Thanks for your kind comments. You can change your color to tan, come on down and catch some sun tan while inspecting the rhombics.
Looks like God is good to me, after all the forced absence from radio and search for new QTH and place for Tesla, we were rewarded. So far lot of cleanup and fixing, but the potential and fertile salty grounds for the antennas are just dream come through.
Recently we had bunch of high tides and flooding, as can be seen from the pictures, but usually over the winter the tides subside and it is easier to walk around and do some antenna fixing.
It will be interesting to compare some classics vs. rhombics and how the modeling reflects the reality.
We are looking for hands and/or brains to join our club, no dues, just sweat or brain equity to get it rolling.

I haqve a Toshiba laptop with 3.2 gig processor which I use for antenna work. I really can't see why I shoulde look for a speedier processor at this time and really it is not that much faster than what you have, if they had a processor that doubled the speed then I would be interested. I use AO-pro which I suppose is a larger program for antennas than NEC4 and sometimes it takes two or three hours to complete a 15 element array and with the processor going at full speed things get a bit hot but then again the processor is not going all the time as one has to print and set things up , so for the total project I see no gain in getting a faster machine. Had a 5150 dell last year of the same speed but oh so many problems with Dell and them refusing to give out repair information that thousands of them were thrown away in anger. They have been sued for a few million but if a failed one had been opened by somebody other than them it can be put down to user abuse where they should not have touched it and waited to see if they were going to be sued. The lawyers by the way get 3 million to sell out all users. Dell suffered a tremendous down turn on all sales last year because of bad service in the face of widespread failures across the board on all their products where they only allowed repaires by their own repair places at an inflated price
with no details of repair for DIY.. Their products are produced by multi suppliers in competition so failures are all over the spectrum and difficult to isolate.To sum up don't buy a Dell!
Cheers
Art

968. how to eliminate mechanical resonance?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-17 10:01:52 UTC
From: francesco.messineo@gmail.com
Message-ID: <1161079312.268757.105110@k70g2000cwa.googlegroups.com>
Source record: 50942

Hello all,
I build one year ago an 8 element 50 MHz yagi. Boom is made with 50 mm square aluminum tubing with
a second square tube on the center of the antenna to strenghten the boom. Elements are made with 20 mm
round aluminum tube in electrical contact with the boom. The antenna is a good performer but it has one
problem: it sounds even in light wind and vibrations come down the mast and are very annoying in the whole
house. The worst problem is that resonance succeeded in unscrewing the rotor bolts. I'm going to use a
special for bolts and screws but I'd like to find a method to avoid mechanical resonance of the antenna.
Does anyone know a good method? Would it be better to add two insulated pulling wires at both ends of the boom (even if probably also elements produce udible resonance)?
Thanks in advance

Francesco IS0FKQ/I8

Dear W1HBQ:

To minimize compatibility issues, I use a stand-alone computer that uses an Intel mother-board, Intel chip set, and Windows 2000. The board has temperature sensors that are accessible through a free Intel computer program. On long runs, one sees the temperatures go way up with 100% CPU use. Obviously, the computer is not a Dell. Dell makes a good computer, but uses non-standard boards. The work horse computer is an old Dell.

The NEC computer has no connections to the outside world and very little software other than NEC4 and the pro-version of EZNEC4. As I recall, the clock is about 2.8 or 2.9 G, 400 MHz FSB, and only 1 GB of ram. I contemplate adding a second 1 GB of ram as some large models do push memory.

If I can find the time, I will benchmark your code.
If you are interested, I can find more details.

It sounds like a really stable mechanical design.

The first thing that comes to mind to me is to damp the vibrations. A spiral wrap of something soft like rubber tubing on the boom and the elements. Unfortunately it would add both weight and wind resistance. Also it would contribute to maintenance. I doubt it would weather well.

The next thought is to try some soft sleeves randomly placed on the elements and boom. I would be inclined to use chunks of tubing about 75mm (3 inches?) long and secured with cable ties protected with black tape. Splitting the damping tubing should make it easy to install.

End caps on the elements and boom are a given but if drains are not provided for each instance water will collect and burst the tubing by freezing.

I hope you have an easy way to get at the antenna for experimenting!

I'll admit to not being an expert on this... However here are some points to ponder.

- The NEC2 etc executable more or less runs in a DOS window. I would guess that it runs primarily in realmode and swaps its data array in and out of high memory. Kind of like the EMM of old. Does this mean it is only a 16 bit app and therefore a waste on a 32 bit processor? This is a similar logic one applies when using a RISC workstation for CAD work.

- I had thought that to a degree software has to be aware of the dual processor/core capability before it can use it. I would think that a "dos box" probably isn't aware of same. This would explain 50% use.

- If you are doing a lot of modeling it may be worthwhile setting up a networked pair of PC's. One that has the user interface and the other doing the calcs. With some modification to the bat/cmd file that calls the NEC exe you could hand the task off to the other machine quite easily. Setting up a queuing function will be the way to go. This would then also free you up to use a purpose built processing engine, possibly even use Linux or even a later DOS version.

Am prepared to be shot down on any of this!

Cheers Bob

Lots of commercial antennas come with rope inside the elements for
mechanical damping. Just find some dense and preferably synthetic rope
that just fits inside the elements. If itï¿½s a vertical antenna, cap the
top elements to keep rain from entering, otherwise leave the elements
open so any moisture will bake out in the sun.

Take a sheet of rubber (say 3-5mm thick) maybe 150mm long and the circumference of the element wide. Make 3 equally spaced cuts 70% of the distance of the long dimension. It will now look like a 4 fingered hand shape!

Using a hose clamp tie this rubber sheet around the uncut end around the elements at some convenient place. The idea being to damp mech oscillation. Maybe 1/3 the way down each element but I haven't exactly thought about where the best place would be.

It may slightly detune the antenna but I haven't thought that through either!

Hello Antenna-Lovers,
I have a "few" antennas on my small lot. I have NOT yet tried
a vertical. I know the need for a GREAT radial system is very
important for success. Does anyone out there know of a device to lay
and set these "wires";off a roll maybe, into the ground ??? Then all
you would have to do is CUT them to the length and attach them. Maybe
a thin wheel 6 inches or so with a grove on the outter edge.....
I don't know. HAS anyone seen anything like this ?? Would it work ?
THOUGHTS ??!!?

As opposed to actually digging trenches or even slits in the ground for radials. I chose to lay them on top of the ground and held them in place with 1 1/2" fence staples. Then I easily covered them with soil from a few wheelbarrow loads. I chose to do this in the dead of winter (no snow in Mississippi) while the grass was brown and very short. Next summer the grass grew and covered the entire "radial field". I used 72 radials total for my Hustler 5-BTV.

I have a 1962 Lafayette catalog that has a page of Finco TV antennas. No ham stuff. Your 2m Stinger is probably that vintage, or older. Also have a 1964 ham catalog, no Finco anything in that.

Hi Francesco,

You did not describe the vibrations, so this may be off base. If it is a "sound", then perhaps the tubing is acting like a flute. Plugging the ends of the open tubes would stop the sound. It may be necessary to leave a small hole for drainage.

My basic experience has been that it takes about 120 half-wave radials to
make a really GOOD ground. But 16 radials the same length as the antenna's
height will get you within 3 db of that. Want those 3db back? Just put up
a second vertical and steer the pattern!

Someone queried
>> Why are they asking for my social security number?

The number is issued to an individual by the Social Security Administration, an agency of the federal government. Its primary purposes are to track individuals' Social Security benefits, and to track individuals for taxation purposes. In recent years the SSN has become a de facto national identification number.

Nuff sed ??

I don't know. When it comes to adressing range, normal windows
application can only adress a max of 2Gb (appr 11000 segments) out of a
maximum total of 4Gb, if available. I know from experiments at work
using VMware system virtualization, where max memory is also an issue,
that for some hardware special work-arounds are available to increase
the 2Gb limit to a max of 3Gb.

Yes, one would normally say so, but when looking at both processor
utilizations one showed a load of appr 40%, the other of appr 60%.

I said de facto.
Certainly SSN was not intended for ID - but try and get a driver license,
Ham license, or bank account without giving your SSN.

Was it a solicitation to renew your license through a VEC? If so,
don't do it; go online to the FCC site and renew for free in just a few
minutes. License renewal does seem to require your SSN, though.

If it was just a random request for info, why give it any more thought
than you would any other junque mail? If they provided a post-paid
return envelope, either (1) fill out the info with whatever you want
(names like Donald Duck, and SSNs with too many or too few random
digits work well), or (2) stuff it with all the other junque mail you
have handy and drop it in a mail box (or both 1 and 2).

Cheers,
Tom

> on a 32 bit processor?

I have no experience with NEC2 at all so my comments are not specifically about that application.

I just want to point out that running as a "console app" does not necessarily mean the app is 16-bit. Using a modern compiler one commonly builds 32-bit applications, both console and graphical user interface. One would have to use an 'ancient' compiler to build a 16-bit application. If NEC2 was built a long time ago that may certainly be the case.

[more editing]
> - I had thought that to a degree software has to be aware of the dual
> processor/core capability before it can use it. I would think that a
> "dos box" probably isn't aware of same. This would explain 50% use.

Absolutely. If the application in question is a single threaded application then it will NOT be able to directly take advantage multiple processing units. (It's single thread may well be switched around between multiple processing units, at the whim of the OS, but only the single thread will run.) You are correct that a single threaded application running a CPU intensive task would likely show 50% CPU utilization on a dual core machine.

Any application written for windows must be designed and written specifically to use multiple threads of execution in order to directly take advantage of multiple CPUs or multiple cores. And, yes, console applications *can* be designed and developed to be multi-thread capable.

Almost conversely, just because an application is multi-threaded does NOT necessarily mean that it's threads will be run on separate processors. It is (mostly) up to the OS to decide which thread runs on which processing unit, at what time and for how long. Think of an application with 10 threads running on a dual core machine.

Threads are still pre-emptively interrupted so that other threads can gain access to compute resources. The machine you are reading this message on is probably switching between 30 to 100 active threads right now.

One big advantage of a multi-CPU or multi-core machine is that when running a highly CPU intensive task (as I gather these modeling applications must be) the other CPU or core is still free to serve up

CPU cycles to the OS and any other applications that are running. This would make the machine feel more responsive to the user.

Sorry to ramble on..

999. Re: how to eliminate mechanical resonance?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-18 00:47:03 UTC
From: Jim - NN7K <NN7K@NOWAY.NET>
Message-ID: <bQeZg.14995$vJ2.3287@newssvr12.news.prodigy.com>
Source record: 50974

Also, be aware that you MUST eliminate that
resonance ! Many years ago, myself (and
another ham) obtained the 6 meter moon bounce
array from a well known ham (he built it, got
echos, than abandoned it- reason, at that time,
he was the ONLY op capible of 6 meter moonbounce!
helped the owner of the first half put it up
on 5 inch irrigation pipe! The array worked well-
but the wind started oscillations in the elements.
The elements began to shear off from metal
fatigue, at the point where they went thru the
boom. Same happened to mine, even as stand alone
yagis! These had elements of 6061-t , 5/16 inch
dia. tubeing, if memory serves.
Translation: IF allowed
to continue, look for the elements to start
breaking off, at some point in time! Would agree
that the insulating foam might be enough to
stop the oscillations in the elements. Good luck
Jim NN7K

Why? Do you fear us working out of band Frenchmen? We could do that
just as well on 6 Meters.

Robesin is absent. Lots of uniques showing up. Maybe we need to run
RRAP through a contest logging program.

NBS yagis were quite horrible actually. Not good gain, horrid
bandwidth, high sensitivity to build errors , crummy patterns compared
to anything since the early 90's. Don't bother.

Sorry, I didn't give an alternatives in my previous email. Please see
the K1FO series in the ARRL antenna books. They are among absolutely
the best possible, very replicable,, low build sensitivity, and fairly
short to very long boom plans are available.

If you do not have one of the ARRL Antenna books available, I, or others
here, have copies as needed.

Most of the antenna work I have done was with 20 - 40 MHz 386 class processors using YO, AO, AOPro. The speed is not really needed so much as an understanding of what is happening and a guiding hand that knows how to tweak the optinization if that's what you are doing.

My longest run was about a month with a 20MHz 80386 plus coprocesser on a wasted effort to make a 2/220/432 interlaced beam with regular (parallel) elements. Not really possible to do well that way, but can be done another way after you know how. Which I did not learn, of course, for another 15 years. hihi

The faster processors, when optimizing, are actually a pain, as the optimization often runs away before you can pause and tweak it.

Also be advised that one of the best known, best designed set of antennas, the K1FO series, was done on a PDP-11 (or microVAX?) running a custom version of BASIC that had been tweaked to do complex math as I remember. And while he spent what might now be considered large amounts of time, he still managed to make a series (10 elements through 40) of practically unimprovable long yagis in a few months.

The speed available nowadays is more than adequate. The memory available now is probably much more helpful.

BB I belieeve you have mentioned passing a code test at some point that
would allow you fullaccess to hf today I could look up your license or
you could tell me

If these are hollow elements simply put small rope inside of them and
then seal the ends. This will dampen the sound, and have the added
benefit of possibly reducing work hardening of the elements.

Amazing; A new ham is excited about getting his ticket and these clowns
get into his face about CW.

Next we will hear more griping about the hobby dying. No wonder. Just
read these posts, who would want to be associated with such clowns. I am
always amazed these clowns are so familiar with CB model numbers etc.

Indeed we could dispense with much of the technical qualifications some day. The technical part is basically an attempt to make sure the amatuer is competent enough to operate their equipment in a maner that does not interfere with other services outside of his designated allocation of spectrum, in other words, within FCC regulations. At such a time when all equipment is made idiot proof and all hams use store bought idiot proofed gear we may see this.So far the one experiment at this has failed. You think you have something idiot proof and then guess what, someone makes a better idiot. So I am not worried about requirement of theory going away. As far a CW is concerned to gain the privledges hams have today they had to show they were a national asset. Part of being that asset was our ability to process emergency traffic should the need arrive. At the time CW was needed to accomplish this. It is no longer needed to meet our obligation of service. OF course this begs the question, can we fullfil our obligation. To this I believe we can, but are we really needed. CW has been replaced by other technologies, it would make more sense to require typing skills than CW, an idea I dont think is so bad even though I may have trouble with twenty wpm on a keyboard.

The "service" provided by the Amateur Radio Service
is a service provided *by* the federal government
to the citizens who meet the amateur radio licensing
requirements. There is no governmental requirement or
obligation that amateur radio operators render any public
service at all. Amateur radio licensees are not even
required to own a radio.

"Service", in this context, is just an administrative
division of government.

You Know i think we can and general do fufill our service obligation
althought I see wht we wil as More holding the fanks and protecting
the abilty of EMS to do it jobs and leave us to keep the gal looking
for here cat off their backs. I honestly think that much of what the
EMS see as our value in most areas

but typing (with maybe the option of some other test like solderiring
or anttenan making the biggest problem with the CW is IMO the fact it
tries to stamp us the hams out in single mold

which explains the vitriol of the some the ProCoder the Nocoders are
rejecting the mold they fit so well into. I would love to see a system
where there were severlal possible tracks to advance (asumming we stay
with something like the incentive license system the current system
and any likely future of it ivolves tring to make us all the same
which we never were and will be less and less of in the future. Trying
to dicuss my efforts and sucesses and failures with EME ops is like
trying to speak in sancript to crowd speaking latin

1018. SteppIR's new 40-30M dipole add-on

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-18 04:10:59 UTC
From: jawod <jawod@fuse.net>
Message-ID: <eb35a$4535a9f5$4831cd39$10358@FUSE.NET>
Source record: 50892

A short while ago, I posted about an idea of a sort of homebrew "steppIR" variable Moxon. Responses indicated that the Moxon design required critical lengths and distances for the folded arms in the design. I.e., this design was not feasible.

In the newest QST there is an ad for SteppIR's 30-40 M add-on element that appears to be similar to what I was talking about.

How would this "folding" dipole behave and what is the difference between what SteppIR has done and a theoretically variable Moxon?

Thanks

John
AB8O

John,

The Moxon is a beam that relies on the element end gap to set up the feed impedance and directional properties. You basically need to mechanically scale the whole array, width, depth, and gap in order to keep it working like a Moxon.

The SteppIR curved dipole thing that goes down to 40m is just an end loaded dipole that uses a transmission line stub as the loading.

It's just a regular dipole until the element goes around the curve, then the doubling back adds a transmission line stub to the ends of the dipole, bringing it to resonance at a lower frequency. I tried it in EZNEC.

This would be a fairly buildable antenna except for the sliding contacts at the feedpoint.

Dan

The sound is low frequency, I'd say less than 100 Hz with amplitude
modulation of 1-2 Hz probably
due to boom vibration. I thought about flute effect but I think it
would be an higher pitch in that
case. I read many interesting suggestions though, I hope to be able to
try some of them in the next
week end.

I won't debate the differences in patterns, as I have no data on the patterns for the NBS designs. In the ones I've built, gains measured were pretty close to what they claimed and the claimed gains of the K1FO style antennas from Directive Systems http://www.directivesystems.com/antenna4.htm (for the same number of elements) is usually within a quarter to a half of a dB of the claimed gains of the NBS designs. I didn't notice a high sensitivity to build errors. I used the design lengths and diameters of the elements on a wood boom. On my 222 version, I used the T match (same thing as the K1FO designs) and all I had to do was shorten the driven element to get zero reflected power (which was expected since you need to make the driven capacitive to tune out the inductance of the matching rods). Not sure what you mean by horrid bandwidth...are the NBS designs too narrow or too wide? Again, I've never noticed that as being a problem because I only use my (222 for example) antenna from about 222.100 to 222.150.

I passed the Novice exam in Nov 1986. 5WPM. I'm presently a General,
so I'm fully qualified to work out of band Frenchmen on 6M or on HF.
Maybe they'll even put me in for the ARRL's A-1 Operator Club.

Don't make it complicated! Complicated equals heavy!

You most probably suffer from the effects of turbulence combined with harmonics from the aerial design itself.

The immediate solution is to do what you do with high chimneys and car radio aerials - you wind a thin spiral round the full (most?) length of the aerial rods. This will break most of the turbulence. You choose lightweight and thin material for this. Try a couple of materials until you are happy. Also, bear in mind that it might only be one part of the aerial that generates the problem!

By adding ropes etc, you just contain the result of the turbulence and the harmonics! By adding the spiral around the antenna rods, you have a good chance of eliminating the source of the problem which is the rods being susceptive to air turbulence, created by the environment as well as the aerial construction itself.

The reasons for adding spirals on high rise chimneys are twofold, first to create a controlled turbulence as an added up draft as well as eliminating the possibility of creating a self oscillation due to the air pressure/turbulence and the harmonics generated in the design.

By adding these spirals, your aerial will be susceptive to icing at cold weather! Check so that you don't get a crashing aerial because of heavy ice coating!

Cheers

Dan / M0DFI

No, I am talking about the service we should be providing. In the spirit of JFK's "ask not what your contry can do for you speech". You are correct that there is no requirement as defined by law but there certainly is a moral one that should be defined by your character.

Thanks for all the information everyone...
The only ARRL antenna book I have is the one on wire antennas, If you could suggest one that covers yagi antennas in detail, I am sure they still sell it. I think that I could build one a lot cheaper than buying one and learn something at the same time.

I would like the best gain possible (who wouldn't) However, I need something that has the smallest lobe(s) off the sides and back. (I know the two more or less coincide with each to a large degree.

To give you an idea of what I am trying to do...I have some land in Richlands NC. I am a member of several ham clubs in the Charleston,SC area that has repeaters fairly close to the SC,NC state lines. I would like to be able to make it into one of those repeaters from Richlands, NC. (that may only work when the bands open up every now and again)
I do not want to key up every repeater on the same freq. to the sides or the back of the antenna.
So I bow down to the elmers and those who can point me in the right direction. BTW. the antenna will be at least 60' high but possibley up to 110' high depending on tower funds when I move.

Im good at QRZ and ARRL
Thanks again
Joe KI4ILB

JFK's speech contradicting this country's founding
principles was just democratic rhetoric. This country
was founded "for the people" NOT for the government.

New Hams just don't want to modernize, they're lazy and don't want to have to learn anything. I'm a 20 wpm Extra and the code requirement didn't stop me from modernizing beyond a microphone and CW. So don't believe anyone that says CW is killing ham radio. They're just sick, lame or Lazy.

If CW has been replaced by other technologies, why aren't more amateurs doing the modernized modes? It's because they don't want too. Ham radio has been dumbed down and we can't even force hams to use them to be proficient communicators.

CW isn't preventing the modernization of ham radio, Laziness is.

Thanks John.

People that don't want to have to learn anything for a ham
license really hate me. 11 meters dead or something? You
seem to be spending a lot more time on the internet lately.

SC

That's what you all want. An easy way to get a lot of people a ticket. You don't care if they can communicate or if they will be an asset to the service. Sometimes I wonder if you're not all getting kick backs from the ARRL.

WOW, Top and bottom posting, Are you bi like Markie?

If ham radio dies it will be the dumbing down that killed it.

I'm motivating them. And when I catch them on the air, they have an
enjoyable and educational contact.

When they find out CW, RTTY, packet, PSK, SSTV, are fun, they have just
stepped in to a much larger ham radio, than one with just a ham talking on
a microphone.

Comments like the dumbed down item and the CB item will NOT motivate them.
To motivate them, simply say "Great, how can I help you explore all the
aspects of ham radio".

> When they find out CW, RTTY, packet, PSK, SSTV, are fun, they have just
> stepped in to a much larger ham radio, than one with just a ham talking on

That is a much better approach so long as you don't go on and on about
"dumbed down" licenses. The people taking the test have no control over the
level of tests required. Simply show them the wonders of ham radio without
comment on your personal opinions about dumbing down, CB, etc.

1049. CW isn't preventing the modernization of ham radio.

Newsgroup: rec.radio.amateur.antenna

From: Merlin-7 KI4ILB <merlin-7@sc.rr.com>
Message-ID: <naAZg.925$337.232@southeast.rr.com>
Source record: 50839

Anyone that can not pass the 5wpm code...
Does not want to spend the time to learn the code...
Does not have the time.....
or what ever....

I can see where some peeps want the code dropped after all they do not test you on PSK or SSTV, however ...I do think that the 5wpm should stand. In an emergancy it may be needed. (to tell the truth, I took the cw test at 15wpm with the 5wpm pause between letters)
I can do sstv and psk and have been playing with aprs.
my 2 cents
Joe

From: "Slow Code" <my.mail@no.spam>
Subject: CW isn't preventing the modernization of ham radio.
Date: Thursday, October 19, 2006 01:10

New Hams just don't want to modernize, they're lazy and don't want to have to learn anything. I'm a 20 wpm Extra and the code requirement didn't stop me from modernizing beyond a microphone and CW. So don't believe anyone that says CW is killing ham radio. They're just sick, lame or Lazy.

SC

His statement was "Ask not what your country can do for you but what you
can do for your country"
I dont remember the word government being mentioned in it.

The words are true even if he was less than sincere. If we are not this
country then what is. This country is "we the people" so ultimately it
including amatuer radio is our responsibility not that which you call the
government.. . It was a call to service, a call to serve this country, a
call to serve its people.. You are correct on one point. It was democratic
rhetoric but damned good rhetoric. But as my grandmother used to say, "Even
Satan will tell the truth if it serves him".

Jimmie

Such a bitter, inflexible, "my-way or the high-way" attitude might be coming
from a very unhappy person. Pleasant people know how to compromise.

This guy could have inflamed hemorhhoids or a bad home life ... maybe both.

[I've had him blocked for weeks; I caught this little gem in a quote-back.]

Sorry, but I see absolutely NO "obligation to perform
some service [to the nation or community]." That is one
of the myths promulgated by the ARRL and its followers.

The word "service" used by the FCC all throughout Title
47 C.F.R., all Parts, is a regulatory term referring to
a type and kind of radio activity being regulated.
[see Citizens Band Radio SERVICE or Radio Control Radio
SERVICE as two examples in Part 95] Also, as Cecil Moore
mentioned, the government is doing its citizens a service,
NOT the other way around.

If an individual WANTS to VOLUNTARILY perform some service,
then excellent. There is NO "obligation" to do so unless
there is some law requiring it. Personally, I think all
citizens of the USA should do at least one term of Jury
Service. In California there is a state law that eligible
citizens shall serve, for a time and times as stated by
law. [I've done five terms of Jury Service here] Anyone
who WANTS to voluntarily sit in on a court is allowed to
(with some special conditions not permitting certain

trials). Those spectators are NOT obligated to do so.

USA amateur radio service is a VOLUNTARY activity. It is an avocation, not an occupation. In other words it is a HOBBY. It's a fine hobby, tens of thousands of citizens engaged in it. But, it is still a HOBBY. It is NOT "essential" for the good of the nation. It is high time that everyone quit dreaming about imaginary glory of "serving the community" through amateur radio...time to look at what it IS in the real world.

you left out something there is one other type of service to oneself

I do think we are obligated to preform one type of service and
learning something counts

additional in an emergency if we find we can be a of service I'd say
we have a moral duty to serve as humans and citizens and our radios
give ways not avalable to many

another type of real service we can perfrom (although some hams like
Robeson seem unable to do so) is simply one to one diplomacy

I know during the elian Matter I enjyed tlaking abit to few cubans
(helped that I was vsiting florida for part of that it drew an
interesting response from them when I said something like you know if
the case were of people totaly within the USA the father would have to
go the florida himself most likely if he wanted his kid back and
givent he US does not trust the cuban govt...

What about a moral obligation?

Suppose I were driving on a winding country road and came upon the
scene of a one-car accident that had occurred only a few minutes before
I arrived.

And suppose the occupants of the car in the accident needed help, and I
had the means to call for help.

Would I not have at least a moral obligation, if not a legal one, to
call for help?

Suppose the only available communication was by Amateur Radio - would I not have at least a moral obligation, if not a legal one, to use Amateur Radio to call for help?

> Personally, I think all
> citizens of the USA should do at least one term of Jury
> Service.

Even those who are not mentally or physically competent to do so? Would you want to be judged by a jury composed of the mentally ill? They're citizens.

Hundreds of thousands of US citizens.

> But, it is still a HOBBY. It is NOT
> "essential" for the good of the nation.

Says who?

> It is high time
> that everyone quit dreaming about imaginary glory of
> "serving the community" through amateur radio...time to
> look at what it IS in the real world.

Does amateur radio not perform any service to the community, Len?

Paladin ha escrito:

Hello,

You didn't mention the operating frequency. If your plan is to make a quarter wave antenna, the ground system is very important. Maybe there is another option. If it is for the higher bands;

Placing the radials above ground does help. If it is a mono band antenna, try to get a halve wave resonance. That has high impedance, en therefore introduces low current into the ground system. The disadvantage is that you have to make a matching network that transforms 50 ohms to the kOhms range.

If the height is too much, you may add a coil in the middle. This reduces bandwidth and increases the feed point impedance.

Best regards,

Wim

For high gain and vertical polarization, you might want to consider two
antennas stacked horizontally. This will get the antennas away from the
metal of the mast and tower. Somewhere betwee 6 and 8 feet should work.

Mark, are you intentionally posting to the rec.radio.amateur.antenna newsgroup, or have you inadvertantly posted to this group while intending to post in some other newsgroup.

The reason I ask is that your postings are not relevant to the rec.radio.amateur.antenna news group.

If you are inadvertantly posting to this news group, please note and readdress your postings to only the news group that peaks your interest. It is wasteful of space and time to continually post to a newsgroup that has no interest in what you're saying.

Walt, W2DU

1085. Long boom Vs Stacked elements

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-19 19:51:11 UTC
From: art <aunwin@insightbb.com>
Message-ID: <1161287471.864214.198980@h48g2000cwc.googlegroups.com>
Source record: 50859

I thought that I would compare my new antenna before it goes up with
one of my old long boom yagis. I found that tho my new array had approx
the same bottom contour of the main lobe of the long boom yagi the
depth and width of the half power main lobe dimensions were much
larger.
This means that with my new arrays main beam covering a larger land
surface area for contacts
the signal to noise may well be a disadvantage tho I must admit that in
the past I have had mechanical difficulties with long booms. The fact
that the main lobe half power points are broader in all directions I
assume that would be the choice for dx style competitions even tho
noisier but for the all round ham operator what is the best choice for
hams such as myself who is not interested in contests?
I suspect that many hams, especially those with small lots, have
tangled with this question so I would like to know what your descisions
were and why..Now if you are interested in keeping this newsgroup for
antenna style discussions now is the chance to contribute to see if
that is where ham members interests truly lies..
Regards
Art

As others have mentioned, this sort of system may require more
cutting/pulling force than a human arm/hand can provide safely, unless
your soil is fairly soft.

A tractor- or horse-drawn plow blade, modified slightly, has been used
to do this sort of radial-burying for commercial radio stations. A
blade is made out of thin (but stiff) sheet steel, and (it appears
from the photo here) a bent piece of conduit is welded to the back
edge of the blade to feed the wire into the ground.

A picture of such a plow in use appears on page 189 of Laport's "Radio
Antenna Engineering".

Probably uses a standard "3 point hook-up". If so, you can probably use any brand tractor.

>the wire. Has anyone seen this tool, and who makes it ??? Where can I buy one
>???

Do a google search for 'vibratory plow'. If you are in a big enough city you
might be able to rent one for a weekend. I haven't used one, but I bet it
would be great for radials.

Oh my, I have some things to do to make to 4500, isn't it?!

So... 100 new pics are not enough, let me see how many I
can post tomorrow..... will I really carried away with the beauty
the nekked male? Just wait and find out.

1104. Re: Mark, are you listening?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-20 18:21:02 UTC
From: art <aunwin@insightbb.com>
Message-ID: <1161368462.308761.248940@b28g2000cwb.googlegroups.com>
Source record: 50778

Walter,, when these type of people see that this is an adverserial
newsgroup they want to join in.because some people like pouring it on
for auguments sake. Ofcourse they can't enter the antenna arguements
they will make up there own auguements in the hope that you will join
them in the fray,after all they believe they have found a place that
they will be noticed. They are succeeding in their quest as people in
the antenna field also enjoy arguements and adverserial relationships
such as yourself and others who have added to this thread. Lets face
it, this newsgroup is losing favor with hams because of its content.
Over the years I have seen many a knowelagble ham fade away from this
newsgroup in disgust while the small core stays on in adverserial
relationships that continually draws these sick type of people. For
things to change the few perceived antenna experts will have to change
their mind set and not challenge everybody with respect to their
intelligence regarding a subject. But that is not going to happen as
the few self perceived experts have oulasted all the true experts and
now perceive themselves as the Senate for Antennas in this very small
pond that we inhabit. Now we appear to be going thru a stage of
nitpicking
that is always good for auguement starters thus strengthening the
attraction to the sick people. The bottom line is that I believe that a
few of the long term self percieved expert inhabitants really enjoy
adverserial debates but dislike the idea of outsiders taking attention
away from them .So a change in the gradual demise of this newsgroup is
going to continue
until a core group fades away as it has done with many an old type ham
that rejected the CB ers who were interested as outsiders the same as
those who rattle morse code spark plugs who feel the same way towawds
fellow hams who shy away from those who feel what they do is a true
sign of intelligence. Walter, you really should join a group that
research the
different facets of antennas even tho it means swimming in a sea
containing bigger fish as they will stay on the subject of antennas
where their interests really lie. That is not the case for many that
frequent this newsgroup. As with antennas you have to compromise on
many things to achieve your desires what ever they may be..
Regards
Art

There was recently a thread here on the subject of whether morse had saved any lives recently. Well it has in the UK!

Have a look at
http://news.bbc.co.uk/1/hi/england/hampshire/6070444.stm

"Torch used in Morse code rescue.
Coastguards in Hampshire have rescued a sailor who used his torch to flash an SOS message in Morse code."

Ian.

No, this is like looking at a fish underwater and not seeing the fish at all because the light is refracted around the fish.

> .....This is what Clinton was talking about when referring to.....
> :is.....!:

No, more like what Bush was talking about when he said 'Mission Accomplished,' what you see and hear is completely different than actual reality.

W8LNA

1111. A chance to argue about something different

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-20 20:30:41 UTC
From: art <aunwin@insightbb.com>
Message-ID: <1161376241.351732.193630@f16g2000cwb.googlegroups.com>
Source record: 50785

Hi members of the antenna group,
Seems like the group is getting bogged down into sniping, here another chance
to get back to antennas. I tried with another post yesterday but the choice of attention is still to those who want to snipe.

With a driven element you have two circular radiation patterns at each section.
Before you start to focus a beam for gain by adding parassitic elements you must first collect
maximuml radiation to the desired direction.
Soooooooooooo.....
with these two circular patterns from the driven element you fold the pattern in the middle
so that both patterns are in the same direction and the same shape i.e a circle that expands to a larger circle but holding on to a particular half power beam width which is an included angle.
So when we start to add parassitics we are able to deal with this CIRCLE of radiation which then focusses by squeezing of the pattern since it cannot add to the initial pattern.
I think the above clearly shows that for recovering of radiation from the rear direction in any form must produce a radiation pattern to the front by retaining a circular pattern. Now I have achieved
such a transformation of a driven element with a reflector to produce an initial circular pattern via computor analysis which agrees in my mind that rear radiation does nothing fto add to the forward radiation lobe.
This is contrary to the thinking of some pseudo experts on this newsgroup. So what is really happening, take a shot at it even if you do not consider your self an expert since we want your participation as well as the experts who will probably hang back to be guided by what others have to say.
Now we can ignore this posting since it is about antennas.
We can use a sniping tactic by changing the subject to a direction that you want .
You can resort to saying I don't understand the question..
We can debate alternative arguments where you tend to disagree and show why e.t.c .
So what do you want for this newsgroup? (Are you listening Walt)
An augument, a debate as to why a radiation pattern changed from circucular or do you prefer to extend the threads from slow code and others of his type who are not here to talk about antennas. Or should we await a similar question to get back on track from one of the old members of this newsgroup who are unhappy with the state of things?.

Your choice guys ! Are you a follower or a leader?
Regards
Art

no you don't. a single dipole element like a common driven element all by itself in free space has a doughnut shaped pattern in 3 dimensions. the typical cross section you see in an azmuth slice is only part of the story... but continue...

> Before you start to focus a beam for gain by adding parassitic elements

just how do you plan on doing this?? you can't take and just fold a field around???

> I think the above clearly shows that for recovering of radiation from

but you said above that you would do this before adding parasitic elements. what do you think a 'reflector' is?? wait, i can answer that, its a parasitic element!

weather it agrees with your mind or not doesn't matter... it has to be physically realizable. so what is this magic configuration that gives 100% folding of the lobes over themselves?? and what happens in the 3rd dimension?

> Now we can ignore this posting since it is about antennas.

your first idea is the best, so i snipped the rest.

Correct David,
I don't know who you are but you are quite correct in stating that the
question must revolve around an array in space. Now that clarity is
established hopefully the debate will remain professional without
sniping
Best regards

Sniping is fun when done under the clinical supervision of a doktor.
They even have sniping services on the web now that will do the
sniping for you. But I've been a fairly successful sniper just using
the old fashioned manual method of waiting until about 3 seconds
before the auction ends, and firing away with my best shot.
I got a vintage fender super reverb amp for $400 using my sniping
techniques.
Check the usual pricing scheme for those... And mine was recapped
and "blackfaced"to boot.
I've been the victim of sniping myself. It can happen to anyone. I bid
on
some real estate in Arkansas a couple of weeks ago, and some other
sniper bit me in the heiney. But I keep a stiff upper lip through it
all,
and call it another day, another $2.41.. As far as your antenna, I
don't
have a clue. We had a quiver in the force recently, and I've forgotten
everything about antennas. I'm thinking about taking up barefoot water
skiing or something like that to fill my time.

I have been looking at the MFJ-1622 antenna. Part of the instructions
for antenna set up, which you can find here....
http://www.mfjenterprises.com/man/pdf/MFJ-1622.pdf
say to roll up about 30 feet of coax into a 12" diameter coil. This
they label as a choke. This just seems like a "duct tape" solution to
me. Is there a better way to accomplish the same thing? Would a few
ferrite beads on the coax do the trick or do I just have no idea what I
am talking about?

P.S. please check out my new Ham Radio Repeater Database web site.

Looks to me like you're overconcerned about fatique problems. Given a
2M antenna the elements would have to deflect +/- some large amount, an
inch or so, probably more before the bending stresses would exceed the
endurance limit of the types of aluminum alloys normally used to build
yagis. If the stresses are below the endurance limit the element can
deflect "forever" without suffering a fatigue failure.

Further the clue in the description of the original problem indicates
that the deflections are generating oscillations with frequencies in
the audio range. If you do a freebody diagram of the "system" you'll
find it's a rather classic spring-mass with excitation vibration
problem. If you crunch the numbers and calculate the resulting time
period on the basis of the mass of a half-element, the spring constant
of the element and the observed frequency of vibration I suspect you'll
find there's no way the element can deflect +/- fast enough to generate
stresses on the element as high as the endurance limit.

Stuff rope through the element and plug the ends with some heavy goop
to add a bit of inertia out where it'll do some good and call it a day.

Chris;

Your best choke is about 30 feet of coax rolled up into a 12" coil.

This is not a duct tape solution but one that has been used for
decades. It is the cheapest and easiest choke you can use. Others are
better but not easier.

Agreed.

The coil only *looks* crude - especially if you actually do use duct tape. But looks can be deceptive.

With the right length of coax, number of turns and method of winding, such a simple coil resonates with its own self-capacitance and is unbeatable as a single-band choke. With about the same amount of care, a slightly different coil can be selected to give an adequate common-mode impedance across several bands. The design data has been in the ARRL Antenna Handbook for many years, and there's more data about solenoid-wound chokes on the web.

The really crude solution is to use just "a few ferrite beads" without giving any thought to which ferrite beads, or how many, or why.

I agree that the coiled up coax is a good way to go. As far as cheapest ,
with the price of good rg-8 size coax the cost is now about the same as the
ready made chokes with the beads on them. If you factor in the cost of a
ready made center insulator for a dipole the cost could be more. Also 30
feet of coax can be another heavy weight to support.

> am talking about?

I have an EXCEL calculator which indicates that particular coiled coax choke should have maximum effectiveness around ~8 MHz. So it probably does a reasonable job on 40m-20m. Unfortunately, it will reach 1/2WL self resonance somewhere around ~16 MHz and thus be essentially useless 17m-2m because of self-capacitance shorting out the choking impedance. Anyone who says a particular coiled coax choke will cover 40m-2m is mistaken. However, the stress on the choke is reduced because the MFJ antenna appears to be resonant, i.e. a low feedpoint impedance.

Here are some actual measurements.

http://www.k1ttt.net/technote/airbalun.html

In a nutshell, the coiled coax choke works well over a frequency range of 2:1 (conservative) or 3:1 (liberal). The beads in the above measurements work well over a frequency range of 4:1. It's hard to beat stacked ferrite toroids of differing materials as a foundation for an excellent all-HF-band 1:1 choke-balun. I know of no single balun that can cover 7 MHz to 148 MHz well. 1/2WL self-resonance defeats the choking action when trying to cover 4+ octaves.

I recently used an MFJ-259B to measure the choking impedance of 8 turns of RG-400 on a 5.35" form. The choking impedance dropped below 650 ohms at 4.63 MHz on the low end and 28.1 MHz on the high end. 650 ohms is not enough choking impedance for all-HF-band ladder-line fed dipoles. Assuming SWR ranging up to 18:1, which is the case for my all-HF-band 130 ft. dipole, the choke-balun may encounter as much as 8000 ohms looking into the Z0=450 ohm ladder-line.

those vibrations are quite common in 10m and 6m yagis where the elements are made of aluminum tubing. they are from the elements fluttering in the wind (usually just in light wind).

to put a few of the misconceptions to rest...
First this is not a 'wind over the bottle' or flute effect. those are much higher frequency and are easily stopped with caps on the ends of booms and elements. so forget the solutions about plugging the ends of elements and booms for this one.

This problem is caused by 2 properties of antennas about that size coming into phase with each other. the first is the vortex shedding around round objects like tubing or wire. this is an aerodynamics/fluid flow problem that is caused by air flowing around the tubing creating a low pressure area behind the tubing, this sets up two vortices behind the element. at a critical wind speed these vortices start to slip away from the element, and when they do they create an unbalanced force... i.e. if the top vortex sheds first the element gets pushed down, this often disrupts the flow causing the bottom one to shed which then pushes the element back up, which causes the top one to shed again, etc, etc, etc,... the effect alternately pushes the element up and down at a rate mostly determined by the wind speed. the cure for this is the spiral wrappings that you often see on chimneys and power lines. the spiral wrap is a way of breaking up the smooth flow around the object so that the vortices don't have a chance to form in the first place. they have nothing to do with strengthening the object, in fact they add to the wind load a bit, but the breaking up of the vortices is their main purpose.

This vortex shedding problem is there all the time on all types and sizes of antennas, but on most antennas it does not cause the damaging type of vibration you see on some of them. why is this??? as long as the shedding frequency is not close to the element's or boom's mechanical resonance there is no problem, the forces occur but they are out of step with the natural response of the element so the vibration can't build. however in 6m and 10m yagis with commonly used tubing the combination of tubing weight and stiffness happens to have a mechanical resonance about the same frequency as the vortex shedding frequency at low wind speeds around that size tubing... everything is wrong. to make it worse, the added motion from the mechanical resonance makes the vortex shedding worse since the element moves more, causing it to move even more, and eventually fatigue and break in extreme cases. note, that the combination of very stiff larger diameter tubing used in later design telrex yagis down to 15m and 20m also had this problem, i found this when i started picking up pieces of elements and eventually whole elements from the ground under the towers from this effect.

if you don't break up the vortices the other option is to change the resonant frequency. there are 2 ways to go, you can increase the frequency, which is very hard... to do that you have to make the element stiffer or lighter. you can't get much stiffer than the tubing being used without extreme measures, and likewise lighter is generally not an option. so the answer is heavier or less stiff. its easier to go heavier, just fill the element up with something heavy. This can also effect the 'stiffness' of

the element, if the weight you put in the tubing is free to move it acts like a floppy weight and reduces the effective stiffness of the element. this is the combination that led to putting rope into elements. a good heavy hunk of rope (this is not the time for polypropelene) smaller than the inside diameter of the tubing adds weight and flops around effectively absorbing the vibration before it gets going. this gets harder on small diameter tubing usually seen on 6m yagis... on those try either aircraft cable or the plastic coated wire clothes line, or even heavy guage insulated wire.

there are also other ways to stop vibrations like this. i have some 20m yagis now that have a long gap between the 1st and 2nd director, this gap was fluttering in certain winds so i snubbed it by adding a second boom brace rope in the middle of the section with just a little bit of tension to keep the boom from vibrating. electric utilities also use dumbell like spring devices that change the resonant frequency of large cables, these are often seen in pairs on either side of the insulators on towers in flat wind prone areas.

Seems to me, the best choke(s) would be two chokes, one designed
for 75m-15m and the other designed for 12m-2m. I cannot bring
myself to believe that a coiled up piece of coax could ever be
an effective choke over a 40:1 frequency range.

Unfortunately, at approximately double that single-band
frequency, the choke is 1/2WL self-resonant and essentially
useless. Someone on QRZ.com quoted the 2006 ARRL Handbook
as saying the following: "A flat coil (like a coil of rope)
shows a broad resonance that easily covers three octaves,
making it reasonably effective over the entire HF range."

Such a coil is certainly NOT "reasonably effective over
the entire HF range" when used on a typical ladder-line
fed all-HF-band dipole. With a 50 ohm 75m dipole, the
SWR on 450 ohm ladder-line will be 9:1. Worst case, the
choke will see 9*450 = 4050 ohms. An effective choke of
five times that value would be 20K ohms or about 850 uH
of inductance. What do you reckon would be the 1/2WL self-
resonant frequency of an 850 uH coil of coax?

Source record: 50731

Very interesting , why can't you post like this on other threads?

Now back to this post. I have never seen spiral windings on a chimney
and certainly would not put it on an antenna. Ice formation is the
worst enemy for any antenna and spiral windings increases the adhesion
of ice to an element. I will say it again that the best solution is to
make the surface as aero dynamic as possible and to reduce the adhesion
of ice which means no clamps on the element. One must also design
connections of element tubing such that added weight to the element
increases tension that is used to hold the element sections together
such as a telescopic type taper connection which helps regarding air
flow. Making the element lighter also helps because it allows for the
willow tree effect like bending in the wind instead of stiffness that
provide for occillation and fatigue failure.
Putting all these facts together and since I live in the Midwest known
for its wind and ice storms I decided a long while ago to change the
method of manufacture of elements which especially helps today as
aluminum costs go sky high.
First I chose a foundation design which was inexpensive, light,
and telescopic
The 20 feet telescopic fishing pole available for less than $10 on ebay
was the final choice
(I did not use the thin portion at the end) I then placed glass
reinforced tape along on one side to counteract distributed weight
sagging and then drilled small hole along that side
so that urathane foam could be squirted inside while at the same time
exuding air to
provide a long homogenous section of the closed cell type.
Now we get to the conductive surface addition.
Hardware stores sell sticky back aluminum tape for air sealing purposes
which bearing in mind that only material to allow for twice the skin
depth penetration is required is then placed length wise along the
element length thus overcoming joint resistance change and with a rub
down of the surface to remove air bubbles you have a radiating element
that is superior to the present state of the art.
One more point before closing, imagine a 20 pound block of ice hanging
on the end of the element, would the ice hang on to the clamp or
aluminum without breaking the element? If the same ice load was on a
non clamped form of element I just described would it slide off, bend
like it was holding a fish or..... immediately break?

One other point, these telescopic poles made in China appear to be
standardised and thus intechangeable also when home brewing you just
add or remove the added foil at the ends without messing with aluminum
section joints. I changed over to this design years ago when I

homebrewed a long boom yagi with 13 elements so my fold over tower
could handle lifting it
and to this day I use this method for making elements. I have mentioned
this before but I got a lot of hoots and cries from old timers who
object to change and fully expect a repeat of the cat calls.

When hiking just take the sections as is and assemble at site as for
short term closed cell foam is not really needed.
Hopefully some of the younger hams will be attracted to this approach
as the cost is way less than the $1000 required for a manufactured
antenna.
Cheers and beers

Hi John,

The link above is rather facile in its reporting, but so are most of
the pages provided by Dr. Smith (there's something of "Lost in Space"
about them).

Anyway, the science behind this news is found at:
http://www.ee.duke.edu/~drsmith/neg_ref_home.htm
which relates to topics I've offered in this group in the past 3 or 4
years. It comes from the photonics of negative refraction abstracted
to RF.

Boeing Phantom Works, here, has already done the bulk of the work and
their devices are displayed at the pages above (without citation), are
better documented at:
http://www.boeing.com/news/frontiers/archive/2004/august/i_tt.html
and
http://ceta-p5.mit.edu/metamaterials/papers/external/2003/Greegor_apl_2003.pdf

The last is a real paper, not the fluff going around in the popular
press.

> 1/2WL self-resonance defeats the choking action when
> trying to cover 4+ octaves.
>

Can you direct me to more good information (as in NOT sales literature)
about ferrites and toroids as choke baluns?

The ARRL Handbook mentions the use of 1:1 baluns on p. 21.16
(Transmission Lines):
For 3.5 to 30 MHz, the recommended choke is 10 ft and 7 turns using
RG-8, 58, 59,8X and 213 (I don't think I've even heard of the last two)

W2DU has a 50 bead balun over RG-303.

As you may recall, I am using a homemade G5RV and I simply connected
RG-8 directly to the ladderline portion. I can see this connection
right out my window (2nd floor shack). I am unaware of any significant
problems as it is. Should I consider using one of these methods and
re-do my antenna?

Thanks for being one of the experts that doesn't talk down to the "rest
of us".

What?? You're new around here aren't you? Run a search in this group on "w3rv"for the years 1995 thru 2005 inclusive then kindly reconsider your comment.

Any of my online food-fight posts which have shown up in this group recently were cross-posted from Rec.Radio.Amateur.Policy without my intent or knowledge. RRAP was founded to specifically debate the contentious code test issue and I've posted to it many times over the years often in a bit of a combative mode. Which is normal, expected practice in that particular group. Food-fights are *not* normal, expected practice in this group and as your search results will illustrate I *don't* indulge in them in this group.

The problem all the ham radio USENET groups is suffering involves the behavior of a few members of the "ham community" who have no respect at all for propriety and civilized behavior and they're destroying valuable resourses like this group. They obviously come from levels of society which the average ham would not like to have living anywhere near their neighborhoods. For lack of a better way to put it . . It's the same bunch which are turning the HF phone bands into embarrassments.

It's a shame but that's the way it is these days. The only ways out seem to be moderated reflectors and discussion groups. Sad.

I don,t think that is all encompasing. During the last couple of days I have written two new postings regarding the academic side of antennas which is what I thought members wanted but that is not the case, read a few answers that I got which are very few. On the other side of the coin there are more members responding to non the antenna issues with slander
so as with any group the majority rules. Throwing mud is always more enjoyable in the absence of applicable logic, but then it is safer to say what Roy resorts to
"I don't understand "
The days that ham radio pursued the sciences are long gone and this antenna newsgroup
is a perfect example of that We have to recognise that simple fact and find a way to turn it around to our own advantage, or alternatively get a gun and play fire with fire.
As far as being a short time poster that is not true, Over the years I have seen more slanderous postings from the suedo experts of which there is still a few around
At one time such comments were thick and heavy even racial with respect to jews so many knowledgable hams left and were replaced by posters who enjoyed that sort of exchange.

Go to the archives and pick out a name that applies to a self percieved antenna expert bearing in mind that I am a learner and you will quickly come across the worst that you will ever see. As I said earlier some of those early combantants are still having a hayday.and more
silly logic is coming in from all sides to join them. Again count where the majority postings have headed in the last few days to gauge what antenna types really want.
I must exclude Walt from all others since no matter what politeness rules in all of his postings as well as applicable logic. Sometimes I have been driven to a lessor ind of response based on slander given.
Cheers
Art

Hi Art,

I've seen your recent lamentations with Brian (who you forgot to
apologize to for your comments) about the lack of technical comment.
To date, EVERY posting that you've made in several weeks has missed
100% of the following:
1. What frequency?
2. What design style?
3. What gain?
4. What f/b?
5. What f/s?
6. What feedpoint impedance?
7. What bandwidth?
8. What height?
9. What optimum launch angle?
10. How many elements?
11. What spacings?
12. What lengths?
13. What orientations?
14. What method of feed?
15. What forms of loading?

Issues 1,3,4,5,6,7,8,9,10,11,and 12 all require numeric responses.
Issues 2,13,14, and 15 demand ordinary mechanical descriptions of
conventional devices.

If the numbers and ordinary mechanical descriptions do not bear out
anything remarkable, you can be sure this will be a short thread. It's
that simple.

Are you having problems with RF-in-the-shack? If not,
your feedline radiation may be doing you more good than
harm. I'm a purist. I install a very good balun/choke at
every BALanced to UNbalanced junction. Some people are
good and some people are lucky. If you have a current
maximum common-mode loop in the shack, you may not even
notice it. It's those voltage maximums that tend to bite.

The Steppir looks more like linear loading of a dipole. Each side of the dipole bent back on itself to give the effect of the full length without the sides having to be 33 feet long.

The Moxon uses a driven element and a reflector - a 2 element system. The ends are not folded back but go at a 90 degree angle. A Moxon looks like a loop but the ends at the sides are separated by a calcuated distance.

We ran a 40 meter Moxon at Field Day and it was a very fine antenna.

You know, I've always been puzzled by negative refraction. The basis of
positive refraction is that the speed of EMR (say light) decreases

within a given material. In negative refraction, the speed of light INCREASES?

I guess as long as it is less than the speed of light in a vacuum, no laws have been broken?

Hi John,

My first reaction too.

However, when you look at the math, negative refraction is, well,
negative. What you describe (and I initially anticipated) is the
ratio of speed of light and the phase velocity being less than one.
Not the same thing being discussed here.

Another expression for negative refraction is "left-handed."

Anyway, more grist for you to review at:
http://physicsweb.org/articles/world/17/5/3

Cecil makes several different points here.

>Unfortunately, at approximately double that single-band
>frequency, the choke is 1/2WL self-resonant and essentially
>useless.

It's a persistent ham myth that an RF choke has specially good properties when the total length of wire is a quarter-wavelength, and specially bad properties at twice that frequency. When the wire is wound into any kind of coil, neither of those claims is true (except maybe by some rare coincidence).

The choke acts essentially as a parallel-tuned circuit, with its inductance tuned by its own self-capacitance. There will be a series resonance at some higher frequency, but not at twice the parallel-resonant frequency (except, again, perhaps by a rare coincidence).

We don't have any performance data for the particular choke recommended by MFJ (and I'll return to that later) but the ARRL Antenna Book does have some measured data on two chokes, both made from 8 turns of RG213 wound into a coil of 6-5/8in diameter. The first choke is a bunched flat coil, and the second is a solenoid. I took the time to import the data (20th Edition, Table 3) into Excel and analyse it carefully.

The bunched choke has a sharp parallel resonance at about 6MHz, with a maximum |Z| value of about 8500 ohms (could be higher because the data are in 1MHz steps). The total winding length at this frequency is about 0.085 wavelengths - a very long way from a quarter-wave. At other frequencies up to about 30MHz, the choke behaves like a classic parallel-tuned circuit: the phase angle of Z is almost purely inductive (+90deg) below the resonant frequency, and almost purely capacitive (-90deg) above it.

There is NO series resonance at twice the parallel-resonant frequency - that would be about 12MHz, and nothing at all "special" is happening there. At 18MHz, where the total winding length is 0.25 wavelengths, there is a very small wobble in the data, but nothing more.

The series resonance, where the phase angle flips from negative to positive again, is at 31.5MHz, which is totally unrelated to any of the other frequencies above. The winding length is 0.5 wavelengths at 35MHz (where the data runs out) but again nothing "special" is happening there.

Thus there is no evidence whatever for the myth of the "resonant length of wire in a choke".

Turning now to the solenoid-wound choke, the different method of winding has increased the parallel resonance of the same length of cable from 6MHz to 9MHz. This is consistent with simple L-C behaviour, and with the solenoid having less distributed capacitance than the bunched winding.

Once again, this choke behaves almost entirely as a parallel-tuned circuit. There are slightly larger wobbles in the data at the frequencies where the total winding lengths are a quarter-wave and a half-wave, but these "transmission-line" effects are still very minor, and completely dominated by the simple L-C behaviour.

The other difference is that the solenoid-wound choke has a much higher parallel-resonant impedance - almost 16,000 ohms, compared with 8500 ohms for the bunched choke. Because of its higher resonant frequency, the solenoid choke would be useful (Z > 1000 ohms) from 7MHz up to at least 18MHz, covering at least four amateur bands, while the bunched choke would only hit 7MHz.

>Someone on QRZ.com quoted the 2006 ARRL Handbook
>as saying the following: "A flat coil (like a coil of rope)
>shows a broad resonance that easily covers three octaves,
>making it reasonably effective over the entire HF range."
>
That's in my 2005 ARRL Handbook also... but the claim of a "broad resonance" is not supported by the more detailed information in the ARRL Antenna Book. On the contrary, the parallel resonance is rather sharp. It would be fair to claim that a carefully proportioned coil balun with a resonance around 10-14MHz can have a usefully high impedance as low as 3.5MHz and as high as 30MHz... but the impedance won't be spectacular at either end of that range, almost certainly less than 500 ohms. So I'd agree that those claims need to be revisited.

>Such a coil is certainly NOT "reasonably effective over
>the entire HF range" when used on a typical ladder-line
>fed all-HF-band dipole. With a 50 ohm 75m dipole, the
>SWR on 450 ohm ladder-line will be 9:1. Worst case, the
>choke will see 9*450 = 4050 ohms. An effective choke of
>five times that value would be 20K ohms or about 850 uH
>of inductance.
>What do you reckon would be the 1/2WL self-
>resonant frequency of an 850 uH coil of coax?

As shown above, "1/2wl self resonance" ceases to be a valid concept once a length of wire is wound into a coil.... but I do see the point you're

getting at: such a large inductor would have too much self-capacitance to be workable solution. If you were absolutely determined to tackle this extreme problem head-on, the best choke balun would be one that exploits its self-capacitance to give a parallel resonance on the operating frequency. However, a far better solution to this problem would be to avoid the extreme impedance by changing the feedline length.

As for the choke recommended for the MFJ-1622, that comes out at 12 turns of 9in diameter, which seems to be aimed at that antenna's lowest operating bands. On the higher bands, the choke will be largely ineffective because it's too big.

For a more broadband solution based on coiled coax, I'd agree with Cecil's suggestion of cascading a large coil for the lower bands with a smaller coil optimized for the higher bands. It would also be possible to cascade a large coil with a small ferrite choke.

ROFL! What a dipshit.

In the UK, a flashlight is a torch. You're getting to be as bad as Mark
in the Dark. I knew if you two put your cards together you still wouldn't
be playing with a full deck.

Markie is all three all right. His brain doesn't seem to be able to connect the dots. If KB9RQZ would KF all the people he hates, RRAP would be a policy group again instead of a Laugh-at-the-Retard forum.

I'm not against trying to help Markie, but Markie refuses to be helped. That's why from now on he's: "Mark in the Dark"

ROFL, Mark in the Dark

That's my new phrase for Markie: "Mark in the Dark"

We can overlook typo's now and then, but Mark butchers the
english language.

LEARN CW, LEARN TO SPELL Markie.

In the UK, one of the common meanings of "torch" is what Americans call
a "flashlight".

Following Richard's informative links, there is a page on the Duke site
which answers the "velocity of light" question:
http://www.ee.duke.edu/~drsmith/negative_index_about.htm

Near the end, it points out the difference between the phase velocity -
which is what we usually mean by "the velocity" of light - and the group
(or energy) velocity. It's only the latter that is made negative, but
the transport of energy is still in the forward direction.

I know very little about optics, but the velocity factor of EM waves in hollow waveguide is always greater than one, that is, the phase velocity is always greater than the speed of light. In fact, it increases as the frequency lowers, approaching infinity at the cutoff frequency.

What prevents it from breaking any laws is that the group velocity, which is the speed at which any change or information can be sent, is always less than the speed of light.

I suspect that negative refraction is related to this, but will leave it to the optics experts to say for sure.

Richard
You decided to leave school for the Navy so that you can meet a man in every port,
where as I chose the education route. Your desires are definately different to mine as I am happily married to nice lady and seek education.
You look after your own business while I attend to mine and I will ignore the message you send out when you are wearing those tight black shakesperian tights even tho you are lacking the balls in declaring what you are actually looking for l You are bald, lonely, and a forlorn dismal pathetic individual, a former pretty/petty officer.without a mate, Find yourself another avocation like roaming the side streets lin another district looking for what you call action, San Fransisco comes to mind from what I hear, try throwing mud around there.
More continued below

Now to the above sniping comments. Go back to the beginning of those threads and read the first or initial posting which you haven't done as yet and neither did Roy Llewellen,None of the above is relevant to those initial postings. What you did was to wait for other posters to supply an avenue for you to do your normal sniping and Roy came in with his normal "sigh"and "I don't understand" comments, he even backed you up with the idea that rear radiation is used to complement the main lobe at the front, willing to put out trash in the hope of getting a jab in.

All this garbage reminds me of a mathematition named George Green who went to school for a year or so in I believe the 1700s before his father pulled him out of school to join him as a flour miller.
While the grinding wheel turned George wrote down many mathematical analysis but his work was not accepted because as an outsider he used terms that others could not or would not accept. A couple of hundred years later a mathematician, it might have been LaPlace decided to review these thesis and had no bones about substituting terms of the modern day and with minor alterations took on the mantle of a genius where his name is banded around to this day. Most of Geoge Green's work has now been claimed by others tho a few Green's theorems still remain but for the work of one open minded mathematician
who gained instant fame where as others stayed aloof because of the terms used all of Green's work would have been lost. Go back to your college books or somebody elses in your case and look up a few of those famous names in the past other than Maxwell and Coloumb(yes try some who proved many a theorem via mathematics,) and you will find some who followed education for its own sake who made allowance for Greens self home education and gained by it rather than only accepting the company of those who hold their noses aloof.
If something is missing or missnamed it is not much to ask for clarification instead of throwing mud. You may have had a lot of setbacks in your life and how people viewed you
but frankly you chose a certain way of life and what goes around comes around.
Back off of people and live and let live as others have continued to do so in your past
The days will look much brighter and even those Shakesperian plays and the company you keep will not be so deterring and you will enjoy the life you have remaining so much better.
Think about it, does mud throwing really make you happy and content?
What are you really looking for so that your remaining life is one of content?

Please don't imply that I said anything about the total
length of wire - I didn't. What you say is true and I
never said otherwise. Well-designed coils can be modeled
as rough approximations to transmission lines.

> The choke acts essentially as a parallel-tuned circuit, with its
> inductance tuned by its own self-capacitance. There will be a series
> resonance at some higher frequency, but not at twice the

I didn't say exactly twice the frequency and I said it
was an approximation. The chokes at:

http://www.k1ttt.net/technote/airbalun.html

average close to double the frequency.

> We don't have any performance data for the particular choke recommended

> (-90deg) above it.

No one would expect a bunched coil to be very well behaved.
Everything I have said applies to a coax choke wound on
some kind of coil form with some care given to its design.

> There is NO series resonance at twice the parallel-resonant frequency -

Again, no one would expect a bunched coil to be well behaved.

> Thus there is no evidence whatever for the myth of the "resonant length
> of wire in a choke".

You keep saying that as if I said otherwise. I didn't. The
length of the wire is irrelevant to this discussion.

> Turning now to the solenoid-wound choke, the different method of winding

> frequencies where the total winding lengths are a quarter-wave and a
> half-wave, but these "transmission-line" effects are still very minor,
> and completely dominated by the simple L-C behaviour.

The point is that there is a 1/4WL high impedance resonance
and a 1/2WL low impedance resonance that are roughly where
they should be. The 1/2WL low impedance resonance should
be avoided.

> As shown above, "1/2wl self resonance" ceases to be a valid concept once
> a length of wire is wound into a coil...

The 1/2WL self-resonance has little to do with the length
of wire. It is where the phase angle flips at a point of
low impedance. The 1/4WL self-resonance is where the phase
angle flips at a point of high impedance. The length of wire
is irrelevant, a moot point. I don't know why you brought
it up in the first place.

Markie is all three all right. His brain doesn't seem to be able to
connect the dots. If KB9RQZ would KF all the people he hates, RRAP would
be a policy group again instead of a Laugh-at-the-Retard forum.

I'm not against trying to help Markie, but Markie refuses to be helped.
That's why from now on he's: "Mark in the Dark"

SC

The problem with this is that Mark In The Dark doesn't feel he needs help.
In his jumbled mind he is just "defending" his honor. Makes no difference
that HE started most of the angst to begin with, does it? That simply does
not compute in his dyslexic brain. Mark In The Dark doesn't feel that
eighty, ninety, or a hundred posts a day is spam.
I wonder if he abused drugs when he was a kid?

Well, basically nothing. So, at the expense of bandwidth let's run
that list once again:

Hi Art,

To date, EVERY posting that you've made in several weeks has missed
100% of the following:
1. What frequency?
2. What design style?
3. What gain?
4. What f/b?
5. What f/s?
6. What feedpoint impedance?
7. What bandwidth?
8. What height?
9. What optimum launch angle?
10. How many elements?
11. What spacings?
12. What lengths?
13. What orientations?
14. What method of feed?
15. What forms of loading?

Issues 1,3,4,5,6,7,8,9,10,11,and 12 all require numeric responses.
Issues 2,13,14, and 15 demand ordinary mechanical descriptions of
conventional devices.

If the numbers and ordinary mechanical descriptions do not bear out
anything remarkable, you can be sure this will be a short thread. It's
that simple.

Oops! I didn't spot that problem. I should realised that 'torch' would cause confusion among you benighted Merkins. Being British, but having a Merkin daughter-in-law, I am reasonably bilingual these days. It's very interesting how the English language has diverged. However, be assured that, in the UK, we have progressed to using flashlights and torches interchangeably these days.
Ian.

Sorry, but I can say for an absolute fact that your 're wrong. It had
kept me out of ham radio and I know exactly what kind of person that I
am. And before the obligatory "lazy" word is trotted out, I have to
work for the pay cheque that buys the radio, pays the rent for the
building that the radio is in and pays for the tower that is in the
back yard. I have to work extra to pay MORE for a place where I am
allowed a tower, as opposed to less expensive digs.

Honestly, I can't believe how some pro-coders look down on no-coders
with such contempt. I was once a member of a "live steam" model
railroad club. These were larger model steam trains that ran with real
steam instead of electric power. They could be run with either propane
or coal, depending on the individual. The guys who built their
locomotives from scratch NEVER looked down on the guys who bought
theirs from a classified ad. The guys burning coal did NOT call the
propane guys "lazy". We all enjoyed a fine hobby and club meetings
were always good fun and most informative. It was great for a

mechanic, like myself, to rub shoulders with experienced retired machinists who built these locomotives. At one of our "open houses", which were located outdoors at the club track, my daughter took her first steps.

Isn't ham radio supposed to be like that? Is there no camaraderie?

In that case, I suggest you stop making constant references to "1/4WL self-resonance" and "1/2WL self-resonance". If you don't mean it literally, it's a very misleading metaphor.

>What you say is true and I
>never said otherwise. Well-designed coils can be modeled

>average close to double the frequency.
>
We're actually looking at exactly the same data (except that the original reference quoted on K1TTT's site also includes a ferrite bead choke for comparison).

I have graphed the |Z| data for all the chokes (see link to spreadsheet below) and there is no consistent trend. In the following table, Fmax is the frequency of maximum impedance, and Fmin is the frequency of any minimum observable within the frequency range (the 8t 1 layer choke has two very small minima). Ratio is Fmax/Fmin.

Choke Fmax Fmin Ratio
6t 1 layer 24 none -
12t 1 layer 15 31 2.1

4t 1 layer 21 34 1.6
8t 1 layer 12 19 1.6
12 32 2.7
8t bunched 6 36 6.0

Judging from the shapes of the graphs and the table above, I would say
that "twice the frequency" is not even valid as an approximation.

>
>No one would expect a bunched coil to be very well behaved.

Across the whole 1-30MHz band, the bunched choke behaves as an almost
perfect L-C circuit, free from any unwanted resonances. The only problem
with that design is to reproduce the exact parallel-resonant frequency
from one example to the next.

If you say "the length of wire is irrelevant to this discussion" - with which I most strongly agree - why do you persist in using these terms "1/4WL" and "1/2WL" - what dimension of the choke are they referring to?

The Excel workbook at

www.ifwtech.co.uk/g3sek/misc/chokes.xls

contains three spreadsheets.

1. Original data
For all the coiled chokes (same data in the ARRL Antenna Book and on K1TT's site) with graphs of |Z|. There are minor dips at higher frequencies, but they are *minor*, and always in a region where the impedance is so low that you wouldn't be using that choke anyway.

These graphs simply don't support the assertion of a series resonance at "twice the parallel-resonant frequency" - not even as an approximation.

2. Three chokes compared
The solenoid-wound 8-turn choke, the bunched 8-turn choke, and the ferrite choke for comparison. The graphs give details of the Z magnitude and phase.

3. LC model
For the 8-turn solenoid choke. The inductance is calculated from the physical dimensions of the choke, using the standard ARRL formula (winding length assumes close-wound RG213). The self-capacitance is calculated from the inductance and the choke's parallel-resonant frequency. The dynamic resistance is the peak value from 12MHz, and is assumed constant at all frequencies.

Those simple assumptions - a fixed L, C and R, all connected in parallel - give a very good fit to the measured data at all frequencies (only one point has been forced to fit, namely the peak at 12MHz). This shows that the dominant behaviour of the choke is like a simple LC circuit, damped by some loss resistance.

Much of the loss resistance is probably due to losses in the PVC jacket of the RG213. If these losses are actually increasing with frequency

(rather than being constant, as assumed) then the fit at all frequencies would be improved.

This very simple LCR model predicts almost everything that was measured. However, it cannot predict any series resonance at some higher frequency. If Cecil cares to produce a transmission-line model of the same choke that can do better, I'm sure we'd all be interested to see it.

Yes ham radio is supposed to be camaraderie. People are supposed to help each other. The divisiveness stems from the fact that too many no-coders appear to want to change the requirements with no knowledge, experience, or understanding of the requirements. In addition, most of us have experienced people who said they could not learn code but upon questioning find that they did not use a good training method and did not train correctly. Yet when they decided they were tired of waiting did learn it and got their upgrade. Then finding out how useful it was in ham pursuits were glad that they had done it.

So far of each of the reasons that people put forth as to why they can't learn it have been disproven by the example of other people with the same problem having gone ahead and done it. The 5wpm level is obtainable although some of the problem do make faster speeds a problem (constant tinnitus may be a severe problem at 20 wpm for example). My ex-OM had 70%

hearing loss in both ears and severe tinnitus. He passed the 5wpm. I know people with dyslexia who have passed. The blind have passed. Even the deaf have passed using flashing lights or vibrating pads.

Do you have competitions in your model railroading activity? If you enter that competition, you all have to follow the published rules with no exceptions. If it is a competition for the "homebrewers", then those who don't do so can enjoy viewing them but they cannot enter into the competition.

I haven't really been following this thread, so I'll assume it
originated by someone who thinks the code requirement (here in the USA)
should be removed from the license requirements. Personally, I don't
think it needs to be removed because with a little practice, anyone can
do 5 WPM. In fact, I recall a young man of about 5 years old getting his
license many years ago...it used to be written up in one of the chapters
of the ARRL handbook. If you don't want to learn code, we have the
Technician class license for that. Anyhow, where in the rules does it
say a ham is required to know code to possibly save a life one day?
It's just something they came up with to use in testing for a license.
From the FCC rules:

97.3 Definitions.
(a) The definitions of terms used in Part 97 are:

(4) Amateur service. A radiocommunication service for the purpose of
self-training,
intercommunication and technical investigations carried out by amateurs,
that is,
duly authorized persons interested in radio technique solely with a
personal aim
and without pecuniary interest.

One place I worked where we sometimes bid on jobs from the UK kept a list of terms with the UK versus US definitions because of the differences in terminology.

Since I know Morse code, it wouldn't be a problem. Just because a light is being flashed, doesn't mean it is a distress signal. If I were standing watch, I'd make sure that I was conversant with the various distress signals that might be used.

[snip]

Personally I happen to believe it should be kept simply because it is one of the basics of ham radio. Even if one never uses it after, it should be learned at a basic (i.e. 5wpm) level. This later enables the individual to later decide if they want to pursue it to a higher level. If they are not required to learn the basic level, they may forever falsely believe that code is too hard for them.

Ian and Cecil,

I think you both should disclose any ties you might have to the cable industry. (hi)

I haven't been able to find out the proper placement of ferrite beads. Are they placed ANYWHERE along the cable. Do you calculate the transmission length for voltage peaks?

Thanks,

John

All of those concepts are explained at:

www.ttr.com/TELSIKS2001-MASTER-1.pdf

in an IEEE sponsored paper by KB1EUD and K1AON. The first high
impedance self-resonance point of a coil, where the phase angle
changes sign, is called "quarter-wave resonance". (The self-resonant
frequency for a 75m bugcatcher loading coil *IS* the 1/4WL self-
resonant point.)

Under "III. TRANSMISSION LINE MODELING", it says:
"By means of conventional distributed-element theory, a thorny
boundary value problem has been reduced to a very simple RF
transmission line. In fact, the entire design and tuning
exercise ... can now be performed conveniently on a Smith Chart."

"There are a great number of formulae for coil self-capacitance.
None are of particular value for quarter-wave helical resonators
anywhere near the 90 degree point."

A coiled coax choke operated at its self-resonant frequency *IS*
being operated at the quarter-wave (90 degree) point.

I doubt that the IEEE would publish a "very misleading metaphor".

> I have graphed the |Z| data for all the chokes (see link to spreadsheet
> below) and there is no consistent trend. In the following table, Fmax is
> the frequency of maximum impedance, and Fmin is the frequency of any
> minimum observable within the frequency range (the 8t 1 layer choke has
> two very small minima). Ratio is Fmax/Fmin.

What we are looking for is the phase shift from negative to positive.
That would indicate the 1/2WL point.

> Choke Fmax Fmin Ratio
> 6t 1 layer 24 none -

The 1/4WL self-resonant point is at 24 MHz. 48 MHz data is not
given. There is no phase shift from negative to positive in the
given data. The 1/2WL resonant point is not contained in the
data so this set of data is useless for finding the 1/2WL point.

> 12t 1 layer 15 31 2.1

2.1 is approximately 2

> 4t 1 layer 21 34 1.6
> 8t 1 layer 12 19 1.6

Round the 1.6 to a single digit - that's approximately 2

> 8t bunched 12 32 2.7

Bunched isn't well behaved enough to count.

> beaded 6 36 6.0

Beaded isn't a coil so doesn't count.

> Judging from the shapes of the graphs and the table above, I would say
> that "twice the frequency" is not even valid as an approximation.

Someone needs to explain to mathematicians that rounding 1.6
to an integer isn't equal to 2. If I said it was an extremely
rough approximation, would that be better?

> Across the whole 1-30MHz band, the bunched choke behaves as an almost
> perfect L-C circuit, free from any unwanted resonances.

Which means it is not behaving as a slow-wave coil structure.
One might say it is misbehaving and is a very poor design.

> If you say "the length of wire is irrelevant to this discussion" - with
> which I most strongly agree - why do you persist in using these terms
> "1/4WL" and "1/2WL" - what dimension of the choke are they referring to?

I'm using them because the IEEE uses them. I keep telling you
that they do not refer to a physical dimension! They refer to
a measurable condition. The first self-resonance is obviously
the 1/4WL point.

I did make a mental slip-up in my previous posting. I forgot
that the VF of the coil changes with frequency. That would
help explain the deviation away from the times two value for
1/2WL resonance. To illustrate the transmission line
characteristic of the choke, the frequency needs to remain
constant while the number of turns is varied.

Ideally, they should be placed at a common-mode standing-
wave current antinode (maximum). Aren't you glad you asked?

Most hams install the choke at the most convenient
place. However, at the feedpoint of a one wavelength
dipole is not a good place.

A common place is at a BALanced to UNbalanced junction
where the choke can perform the balun function.

Somewhere in there is a very bad joke about "cable ties"...

Cable is much less expensive over here than large ferrite beads imported from the USA; hence my interest in the coiled cable chokes.

>I haven't been able to find out the proper placement of ferrite beads.
>Are they placed ANYWHERE along the cable. Do you calculate the
>transmission length for voltage peaks?
>

The place to start is where the common-mode current would be launched onto the coax. In an antenna fed with coax all the way, that would be the feedpoint. In an antenna fed partly with coax and then with parallel line, it would be at the transition point.

But if the system is physically asymmetrical (eg if the feedline runs back horizontally below the antenna) a single choke may not be enough to solve the problem. In that case, the next place to think about would be a quarter-wave closer to the transmitter.

...Doorbell...

Someone stopped by for a long Sunday afternoon chat, and in the meantime Cecil has provided the rest of the answer.

One additional point. If the above were true, as the
frequency is increased, the phase angle of the coiled
choke impedance would drop from ~90 degrees to zero at
the self-resonant frequency, and then rise back to ~-90
degrees and stay there. But that's not what happens.

In every single case, the phase angle rises toward -90
degrees *and then decreases* as the 1/2WL self-resonance
point is approached. That is a clear indication of transmission
line effects. A lumped circuit simply doesn't act that way.

What lie??

No-coders are missing a major portion of the HR experience. That is NOT a lie!
It is a fact.

Example: you can call yourself a marine two days after enlistment. But, you
become a Marine after completion of basic training! The commitment to success
through a period of trial and learning makes the Marine not the uniform.

No-coders have enlisted in the hobby. But, ...

Ignoring the profanity [when profanity surfaces in a discussion it is evidence that you are losing the argument], Maxwell's Equations are first of all NOT Maxwell's equations. They are Heaviside's Equations [go do a rigorous check].

Secondly, the equations describe physics, not operating practice.

Thirdly, the equations and their understanding are not requirements for a license. Most hams cannot perform the vector calculus or solve the second order differential equations necessary to solve those equations [Many professional broadcast engineers probably can't solve them either]. After 40+ years from my EE degree I know I can't solve them without some refresher math courses.

Finally, increasing one's personal skills in the radio communications art and technique for personal improvement, not $ gain, is the requirement for a ham license, at least here in the USA.

Increasing personal skills ... does not mean becoming an appliance operator.

Jus' wonder.
Does Art read what he writes, after he writes it and does he understand what he wrote? Or are those just fragments of his elaborate train of thought making it onto the I-waves and puzzling the rest of us dummies?
Snip shield on!

Here is the challenge for the antenna designer:
Design antenna that on transmit will radiate with some 15 dB gain in all directions and on receive be capable of sharp beam control in H and V planes, infinite F/b and F/rest of course.

Yuri, K3BU

"BASICS" AND "BASIS" are two different words with different meanings.

Basics include Basis among other topics, while Basis is Basic to any topic.

What is meant here, which you deliberately misunderstand, is that to
obtain the title of "Amateur Radio Operator" you must first understand
"Basic" electronics, Elementary communications "LAW", "Basic" radio
operating procedures, "Basic" radio theory, multiple operating
techniques, including: Voice, Digital, various modes i.e. AM, FM, etc.
Those of us that support the inclusion of a "BASIC" understanding of CW
communications do so because CW is "BASIC" to Amateur Radio
Communications. With out the CW ability you are just a partial HAM. With
the CW ability you have a more rounder understanding of our hobby. There
is no necessity to use CW at anytime in your Amateur Radio lifetime
after you demonstrate the ability to receive 25 letters/numbers/punction

characters within one minute with out error.
One of the reasons that I don't use CW is that years ago when I got my Novice I was in a QSO with a station and it took me atleast 5 minutes to correctly "HEAR" his call sign. I kept running the letters together. So much for my CW ability. I did , however, pass the Element 1 CW test twice. Once for my novice and once when I went for Tech before I got my Novice ticket. This was taken at the FCC examination site.

Remember your opinions are just as valuable as mine and are of equal status no matter what you may think of mine.

> 73, Cecil http://www.w5dxp.com

Why worry about VHF though? Most people wouldn't want to use
their HF wire for VHF. Or at least, I wouldn't. I always use other
antennas for those bands. Seems to me, if you were to use two
chokes, one for 160-40, or 80-30, and one for 20-10 would be more
practical. A good choke for 20-10 "tribander", is 8 turns of RG8 wound
on a 6 inch form. There is no real need to wind in an orderly military
manner,
although some do. I often just throw them together liking rolling up a
rope,
and they work fine. I had to place a small choke on my mobile for 2m.
I kept having problems tuning a 5/8 wave 2m whip I made a few weeks
ago.
Tried trimming, adjusting the coil, etc. No joy. Came to the conclusion

common mode currents were causing me grief, and this is using a hole
mount drilled in the trunk lid. I usually don't have problems with
those..
I wound a small coil from rg-58, maybe 4-5 turns on a small appx 2 inch
dia,
and all my problems were gone.
A coax choke will need to be pretty small to work well on VHF.
I don't really see one made to work the upper HF bands as being very
good. So, in designing one for upper HF, I'd use 30 mhz as the upper
limit. I've got some info somewhere, maybe in the ARRL ant book that
gives appx dimensions for chokes at various frequencies. 30 ft of coax
wound on a 12 inch from would more likely suit the lower bands more
than
the upper HF bands. So I'd use a 8 turn, six inch dia choke for 20-10,
and whatever choke for the low bands. I'd leave VHF out of it, being
most
HF wire antennas are fairly lame for VHF. Heck, on my 706mk2g, using an
HF wire antenna is inviting lots of image problems for receive when
using

6 meters. 2 meters, I use ground planes, yagi's, etc.. I use a 3 el
yagi on
6m.

Well, he did do his statesmanship in Great Britain but he was the First and so far only "Honorary American Citizen".

See Wikipedia. Appropriate extract: In 1963 U.S. President John F. Kennedy acting under authorization granted by an Act of Congress, proclaimed Churchill the first Honorary Citizen of the United States. Churchill was too ill to attend the White House ceremony, so his son and grandson accepted the award for him.

Besides his mother was an American Citizen conferring upon Winnie eligibility for his own status of "American Citizen" should he have chosen to exercise it.

I have not experienced EME or FS-ATV or a great many other areas of amateur radio but I have done CW. I don't do it anymore but I have experienced it. CW is the one mode that can get through under almost any condition. You can (I can't anyway) copy CW in the middle of a thunder storm, using the Aurora as a reflector, using meteor ionization trails as a reflector or just direct point to point contact to accomplish this. Try that with FM, AM, SSB voice or digital.

The problem with this and similar threads is a number of individuals do not feel that they need to learn CW because they don't intend to use it.

A person of "Quality" may never need the proper etiquette to greet the Queen but you had better know how to be considered as such a person.

Just having a little fun with a people divided by a common language.

1244. HF LPF at antenna balun

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-22 20:21:07 UTC
From: yea right <spam@spam.spam>
Message-ID: <pan.2006.10.22.20.21.05.593985@spam.spam>
Source record: 50718

I would like to add a simple lowpass filter to a T2FD antenna I have. My QTH is about a mile from several FM and TV xmitters and I'd like to scrub them off before they even hit the 9:1 balun while in the 490ohm balanced domain using a simple filter. (like two coils and two caps)

Anybody have a link to make the calculations of the components?

Is there a better way?

>Cable is much less expensive over here than large ferrite beads imported
>from the USA; hence my interest in the coiled cable chokes.

The cost of cores from imported from the US in Australia is also very
high.

For those in Australia interested in W2DU style baluns, I roughly
measured the impedance of an inexpensive core from Jaycar using a
Mighty Fine Junk 259B and plotted the results at
http://www.vk1od.net/balun/index.htm . Less than A$20 is probably
sufficient for an adequate balun for 80m to 10m.... depending...

My own view is that the number of cores required for a W2DU style
balun is unrelated to the characteristic impedance (inner to outer
conductor) of the coax as is commonly held, but that the number of
cores / effectiveness varies with location on the feedline and is
highly dependent on the scenario (frequency, topology etc) and the
optimum solution may required more than a single choke.

Ian, perhaps low cost suppression cores are also available directly in
your country, candidates for measurement and reporting!

Owen

PS Interesting plots, better presentation isn't it, the Y axis label
on your phase graph needs a fix.

thusly:

>What lie??

It's not a lie that code has kept good people out of ham radio.

>No-coders are missing a major portion of the HR experience. That is NOT a lie!
>It is a fact.

It's too easy to find hams that know code, used code and hated it.

>Example: you can call yourself a marine two days after enlistment. But, you
>become a Marine after completion of basic training! The commitment to success
>through a period of trial and learning makes the Marine not the uniform.

Poor analogy. The Marines NEED harsh training to be able to do their
difficult jobs properly as lives and the nation depend on them. The
training is not a test of commitment, it is a harsh reality.
Ham radio is just a hobby.

>No-coders have enlisted in the hobby. But, ...

Did you not read my last post? It's right below. The guys who built
their own locomotives did NOT go up to the guys who bought theirs and
say "You are not a real model steam train operator!!!"

It's just a hobby.

No competitions, just a bunch of guys who like live steam model
trains. The club did not exist for that.

Thank you.

BTW it seems that I have been wrong on the attribution of the
observation. Someone else pointed out the another great person made the
comment not Churchill. At least I can't find where Churchill may have
made it.

My apologies for the error but the sentiment still stands.

The spreadsheet at
http://www.ifwtech.co.uk/g3sek/misc/chokes.xls
now includes graphs of the phase information for all the chokes.

[Thank you, Owen - the phase axis label is now fixed .
For anyone interested who doesn't have Excel, Microsoft's free Excel
file viewer is at http://tinyurl.com/cup85]

Coming all the way back to the original question, the data confirms that even though it may look like something held together with duct tape, a coiled coax choke can be an excellent single-band solution. At its parallel self-resonant frequency, it will have a much higher common-mode impedance than a generic string of ferrite beads. It can probably outperform or at least equal a ferrite choke over two or possibly three adjacent HF bands; but being a resonant device, it cannot deliver extreme broadband performance.

In the chokes we're looking at, the low-impedance series resonances of which Cecil complains do not occur below 30MHz. Those resonances exist, but not on the HF frequencies where the chokes would actually be used.

Within the practical working frequency range of all of these coiled-coax chokes, the performance can be accurately described as that of a simple parallel tuned LC circuit, which displays no transmission-line behaviour whatever. Cecil complains that
>One might say it is misbehaving and is a very poor design.
>
That sounds to me like the complaint of someone who has a pet theory to hammer, and is disappointed when he can't find a nail.

I think that's it, really. The graphs themselves say the rest.

Hi Owen,

It is far easier to simply use OpenOffice which is an executable that
will translate to/from Windows Office (any spread sheet, document,
presentation, drawing...). The Open Document format is the mandated
standard of the European Community, if I recall correctly.

As I said, human nature has a lot of negative aspects no matter what the
activity. All one can do is ignore it and do their personal best.

>>Do you have competitions in your model railroading activity? If you enter

Still my point is that when there are rules, one is obliged to follow them
whether they like them or not.

Ian, I think I corrected an obvious typo of yours. It
appeared that you had gotten off by one row. If that
was wrong, I apologize. Here's what you posted:

> Choke Fmax Fmin Ratio
> 6t 1 layer 24 none -
> 12t 1 layer 15 31 2.1
> 4t 1 layer 21 34 1.6
> 8t 1 layer 12 19 1.6
> 12 32 2.7
> 8t bunched 6 36 6.0

There were six chokes. The fifth was bunched and the
sixth was beaded. The bunched ratio is 2.7. It seemed
obvious that you had made a typo in your chart which
I corrected.

From: Merlin-7 KI4ILB <merlin-7@sc.rr.com>
Message-ID: <1BU_g.14963$vK.8060@tornado.southeast.rr.com>
Source record: 50644

On the USS YOURKTOWN in the Charleston, SC harbor a local radio club that I am a member of, has a radio room using a butternut antenna..
It is mounted on an old aircraft carrier sitting in salt water. that is the best QTH for a vertical but my question is......

What is the biggest difference between a vertical and a horizontal antenna other than the obvious? When I use the rig in the Yourktown it seems that I can contact stations a lot further away with less noise than my home QTH.

Is it just its QTH or am I missing something else?
Joe

1271. 10 meter mobile antenna

Newsgroup: rec.radio.amateur.antenna

I just bought a 10 meter mobile rig (25 watt old radio shack rig).

I was planing on cutting down a 102" CB whip to 10 meter band.

Anyone know of any type of antenna that would work better?

Thanks
Joe

> but not on the HF frequencies where the chokes would actually be used.

But, Ian, what about 75m and 40m?

Those resonances above 26 MHz are transmission line effects.
The largest coil is only 12 turns, not nearly enough for 75m
operation. The largest 12 turn coil has a choking impedance
of only 100 ohms on 75m. Scale the choke to 75m and 40-50 turns
are probably required. That would certainly lower the 1/2WL
resonant frequencies into the HF ham bands.

The 12 turn coil's peak impedance is around 15 MHz and its
1/2WL low impedance response is around 31 MHz. If we scale
the peak impedance value to 4 MHz by increasing the turns,
the 1/2WL low impedance response would be around 8 MHz. Such
a choke would be useless above 10 MHz.

Bottom Line: If enough turns are used to achieve a high choking
impedance on 75m, the 1/2WL resonant transmission line effects
will occur in the middle of HF making it useless on the higher
HF frequencies.

> Within the practical working frequency range of all of these coiled-coax
> chokes, the performance can be accurately described as that of a simple
> parallel tuned LC circuit, which displays no transmission-line behaviour
> whatever.

This is obviously a false statement proved by your own graphs.
If there were no transmission line effects, the phase graphs
would all converge on -90 degrees. All of the phase bumps above
26 MHz are transmission line effects. If the chokes had their
maximum impedance at 4 MHz, those 1/2WL transmission line effects
would probably be in the range of 10 MHz rendering them useless
on 30m-10m.

>Cecil complains that
>> One might say it is misbehaving and is a very poor design.
>>
> That sounds to me like the complaint of someone who has a pet theory to
> hammer, and is disappointed when he can't find a nail.

Actually, I was just quoting this web page:

http://www.k1ttt.net/technote/airbalun.html

"- Don't bunch the turns together. Wind them as a single
layer on a form. Bunching the turns kills the choking effect
at higher frequencies." I agree with WA2SRQ that the bunched
coil choke is a poor design. Do you think that WA2SRQ has a
pet theory?

> I think that's it, really. The graphs themselves say the rest.

They certainly do. Everything above 26 MHz is obviously transmission
line effects. If the chokes were designed for the lower part
of the HF spectrum, the 1/2WL low impedance points, caused by
the transmission line effects, would be in the middle of the HF
spectrum.

Scale the high impedance points for 75m and the low impedance
bumps due to transmission line effects will occur in the
middle of HF.

The secret is the combination of QTH and antenna polarization.

A vertical antenna with salt water extending a few wavelengths in the
direction of communication has a tremendous advantage. It produces a
high strength signal at very low elevation angles. You won't get this
with a horizontal antenna unless it's very high, or a vertical
surrounded by dirt, regardless of how good your ground system is (unless
it extends several wavelengths from the antenna), unless there's a
lengthy downward slope to the ground in the direction of communication.

Apology accepted. What you had missed was the statement immediately
above the table, that:
> (the 8t 1 layer choke has two very small minima).
Therefore that choke has two lines of data.

The bunched choke is the one that has a Fmax/Fmin frequency ratio of 6.
A certain amount of mental gymnastics allowed you to claim that 1.5, 2.1
and 2.7 are all approximately equal to 2... so how about 6?

1277. cardiod antenna @ 2.4GHz

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-23 06:58:20 UTC
From: electro <electromagnetic377@yahoo.com>
Message-ID: <1161586700.733839.272750@i3g2000cwc.googlegroups.com>
Source record: 50651

hi,

im designing a cardioid pattern at 2.4GHz, null based measurment.very
few articles dwell on this topic especially in the microwave region.
essentially, the cardioid pattern is a result of the mixture of a
figure eigth and an omni radiation.im thinking of using a simple
monopole(triangular patch) and a dipole(coplanar waveguided slot).
these are my questions,

1. is using a power combiner(wilkinson divider) with the monopole and
dipole as inputs the correct way of producing the cardioid pattern?i
2. are there any other methods on how to combine the patterns?
3. how about the spacing or relative distances between the feedpoints
of the monopole and dipole?

thank you so much!

Thanks for that information, Charlie - it's very useful to know what other systems can see.

>but I did have to reposition
>the graphs which were over the table.

That's how I saved the graphs, so OpenOffice got those layout details right.

Once the graphs have been plotted, it isn't necessary to look at the underlying table very often, because the data can be seen in a popup window by running the mouse pointer along each plotted line. If OpenOffice can do that too, you may find it a convenient feature.

Alternatively, you could drag both graphs away to the right, and then use the horizontal scroll bar to move between the table and graphs.

Roy,
I haven't reviewed the physics of relativity lately, but I 'believe'
that value of C is specified as the velocity of energy propagation in a
vacuum... SInce that limit is not violated when the wave front is
propagating in a medium with a refractive index greater than vacuum,
i.e. C is slower than in a vacuum, then by O'Connor's Law of
Reciprocity the limit will not be broken if the the wave front is
propagating a medium with a refractive index less than a vacuum, i.e. C
is greater than in a vacuum...

Have you heard of a 10 meter mobile antenna??

Hamstix, Hustler, et al make them. Lot easier than trying to cut steel.

I apologize. I jumped to conclusions. The obvious typo
wasn't so obvious after all

> The bunched choke is the one that has a Fmax/Fmin frequency ratio of 6.
> A certain amount of mental gymnastics allowed you to claim that 1.5, 2.1
> and 2.7 are all approximately equal to 2... so how about 6?

As I already stated: What I have said applies to well-
designed coils that can be modeled as transmission lines.
That includes properly wound chokes and bugcatcher loading
coils. A bunched choke is known not to be well-designed.
Quoting WA2SRQ again: "Don't bunch the turns together. Wind
them as a single layer on a form. Bunching the turns kills
the choking effect at higher frequencies."

Bunching also tends to kill the transmission line effects.

How many 75m bugcatcher loading coils have you wound
in bunched mode? :-)

It is a known fact that the VF of these chokes changes
with frequency so they don't behave exactly like a
transmission line. Bunching probably changes the VF
considerably more than a helical wound choke since
the first turn and last turn may be on top of each
other.

You missed LP records. Which are, like everything else he did, just a
bit different than the versions on the other media.

They are supposedly making the radio plays again, and Adams will be
doing one of the characters. I do not remember which one. Apparently
he recorded the tracks years ago.

Now back to our previously interrupted thread.

As long as you only cut it as much as needed to move it up into the
ten meter band it will still be a full length quarter wave antenna.
No, there is almost nothing you could get that is better..... provided
you mount it in the center of your roof.
Now, the interesting question becomes, "If you don't mount it in the
most optimum location, how much is it degraded, and would a loaded
antenna mounted in the center of your roof be any better?"

Realistically speaking, a center loaded (approximately 60 inch long)
antenna mounted on the trunk or roof is a very good compromise.

All those commercial antennas will work better at thinning your wallet. But not at getting your signal out. The only way you'd improve over the signal from a cut-down CB whip (2 minutes work with a hacksaw) is to either make the antenna directional in azimuth which would decrease the signal in other directions, or try making a collinear array. And I seriously doubt that you could get any noticeable gain from a collinear without making it too tall to be practical.

I'm glad that some hams are still willing to reach for the hacksaw instead of the wallet. Go for it!

I've never actually really compared bunching to helical wound.
The one they specify to build for my triband yagi is a helical
coil. On that antenna, I've used both methods, but not at the
same time to really compare. I didn't notice any real noticable
difference in operation though. I was just looking at the small
choke in my trunk for 2m. It hangs from the trunk lid, and is
tie wrapped. It was about 2-3 diameter, and about 4-5 turns
or so, bunched together. For the purpose I used it for, it
worked great. But it could well be possible what you say about
the higher frequency operation. I do know a bunched choke is
a whole lot better than no choke at all. :)

I could probably torch that bugger off in about 15 seconds.. :/
Might look kinda funky on the tip though. I agree. What is
has is about as good as he's going to get. As long as it's
grounded to the car well, preferably on the body somewhere,
it's going to work great. Any other whip is probably going to
be inferior as far as a 1/4 design. But it is possible for a roof
mounted half size whip to equal a full 1/4 wave with a lower
or poor ground. I'd use a bumper mount as a last resort.
A side body mount with a ball mount, or even trunk mount
would work a lot better. That whip on a roof would brown the
food. Not very practical though as far as trees and drive thru's.
A trunk mount is possible though. Heck, my mobile antenna
is way tall. But I don't really care about looks much.. I recently
bought a third small car to save gas when I don't need to drive
the trucks. I put it's antenna mount on the trunk lid with reinforced
plating underneath to keep from ripping the trunk lid apart.
Hondas have thin sheet metal... :/ My 11 foot antenna would flex
that thing like crazy with no plating underneath. Wouldn't last
3 hours before I ripped a hole in the trunk. I had to do the same
with a monte carlo I once drove.

OK, the next problem I will be haveing is The interaction between my 10 meter whip and the 11 meter whip.
Removeing the CB is not an option, I need it for work.

I will be adding the 10 meter whip to a 4door Dodge ram pickup.The two antennas that are on the truck now are mounted with stake hole mounts (the holes in the bed rail behind the driver and passenger)

The 11 meter and the 10 meter rigs will not be on at the same time.

How would you place the antennas to keep the interaction as low as possible or use the ineraction in some way.

Thanks
joe

What you've got is one antenna with two feed points.

Any use of the interaction will result in a directional pattern, making the signal stronger in some directions and weaker (perhaps a great deal weaker) in others. I suspect you don't want that.

The best solution would be to open-circuit the unused antenna at its feedpoint. This could be done directly with a relay, by short-circuiting the rig end of a feedline which is an odd number of electrical wavelengths long, or open-circuiting the rig end of a feedline which is an integral number of half wavelengths long. It would be a good idea to make the switch(es) operate from the rigs' power, to prevent accidentally transmitting into a shorted or opened feedline.

The two bands are too close to make most other methods impractical.

>are probably required.

Sorry for the delay in replying, but I just did something completely radical for this type of discussion: hauled out some cable, made some chokes, and measured them.

These chokes were intended to be like the ones recommended in the ARRL Handbook for 3.5MHz and for 7MHzz, both using 22ft of RG213. What I had was actually 21ft, and this length was wound into a flat coil having various numbers of turns. The choking impedances and phase angles were measured on an N2PK Vector Network Analyser.

Ten turns made a choke that had >1000 ohms impedance from 3.4MHz to 6.4MHz, falling to about 650 ohms by 7.3MHz. This makes a respectable two-band choke, if you judge it by the criterion of needing about 500 ohms minimum impedance, but it's a stretch to cover both bands from edge to edge (9 turns was probably a slightly better compromise). Moreover the maximum impedance of 17k is "wasted" between the amateur bands at 4.6MHz.

That confirms our shared suspicion that the Handbook's claim of "a broad resonance that easily (sic) covers three octaves" is over-optimistic. Where the coiled-cable choke really excels is as a single-band device, exploiting its extremely high peak impedance at parallel resonance.

Without needing to change the overall length of cable, the peak resonance can be shifted to different frequencies by increasing or decreasing the number of turns, although I couldn't persuade 21ft below 4.6MHz (10 turns) because the bending radius was becoming too small for RG213.

However, it's perfectly clear that Cecil's estimate of "40-50 turns"
needed for a 75m choke is way off.

Right conclusion about the choke being useless a long way above its peak
resonance - but not the right reason for it. The true reason is the very
simple property of a parallel LC circuit (the inductance of the coil,
resonated by its own self-capacitance) which means that far above
resonance its parallel impedance drops to a very low value. That's what
makes it useless at those frequencies.

The 4.6MHz choke does have series resonances at about 23MHz 33MHz ,but
those cannot be said to affect the performance of the choke in any
practical way, because the choke doesn't have any usable performance at
these frequencies anyway.

Cecil keeps resolutely ignoring the reservation: "within the practical
working range of the choke".

Within the frequency range where the choke has a practically useful
value of impedance, there are no - repeat NO - signs of transmission
line effects. Its behaviour is purely LC, its own inductance resonating
with its self-capacitance.

>>Cecil complains that

>coil choke is a poor design. Do you think that WA2SRQ has a
>pet theory?
>

I think WA2SRQ's advice is one-sided, because it fails to recognize the benefit of bunching the cable together - namely that it moves the whole resonance curve downward (due to the increased self-capacitance) without needing to increase the length of cable. For someone who wants a low-band choke, that is a Very Good Thing. The poorer performance at higher frequencies is the obvious natural tradeoff for having moved the whole resonance curve downward - but that doesn't make it a "poor design".

>> I think that's it, really. The graphs themselves say the rest.
>
>They certainly do. Everything above 26 MHz is obviously transmission

>of the HF spectrum, the 1/2WL low impedance points, caused by
>the transmission line effects, would be in the middle of the HF
>spectrum.
>
>Scale the high impedance points for 75m and the low impedance
>bumps due to transmission line effects will occur in the
>middle of HF.

Hands-on measurements prove otherwise - the spurious resonances stay pretty much where they were, above 20MHz.

As stated above, I measured a choke which is resonant at 4.6MHz. It has over 1000 ohms impedance at 3.5MHz, rising to over 2k at 4MHz, so it would be a very good performer on both 75m and 80m.

But above the main parallel resonance there are no bumps in the impedance or ripples in the phase response at any frequency below 20MHz - none.

It is ridiculous for Cecil to describe such a choke as "misbehaving and a very poor design". On the contrary, bunching the turns to increase the self-capacitance has proved a very good way of moving the main resonance downward to make an effective single-band choke for 75/80m, while leaving all the unwanted resonances parked above 20MHz.

Welcome to the new world of ham radio. That'll be thirty-nine dollars
and here's your complimentary QST and CB radio.

SC

1300. G5RV and 68ft of coax

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-23 23:52:49 UTC
From: John Phillips <k1bxi@verizon.net>
Message-ID: <lBc%g.1025$%T3.310@trndny03>
Source record: 50674

I have always seen mentioned many times when someone writes about the G5RV antenna that you need to use a minimum of 68 feet of coax connected to the 30ft of twinlead or ladderline. I'm pretty sure that you can blame me for that urban legend. Sometime around 1965-1967 several of us in Maine were fooling around with the G5RV configuration on 75 meters. Some with good results and some with not so good results! A ham by the name of Charlie Murch decided to manufacture the antenna, which he called the 51-30-51 for obvious reasons. He sent many of us a prototype to test. In that era the rigs were tube finals with a pi network output which could handle a modest range of input impedances. Antenna tuners were not in vogue and Lou McCoy's design of the "Ultimate Transmatch" was just coming upon the scene, the granddaddy of most of the tuners used today.
So with my trusty HQ129X rcvr and DX100 xmiter, a Jones MicroMatch swr bridge plus a brand new Omega T noise bridge I set out to solve the mystery of the G5RV. The first antenna was erected about 200 feet from the shack and 35 feet in the air with 200 feet of coax hooked to it. Worked good and showed a less than a 2.1 swr on 3.940MHz. The next location for it was closer to the shack and required only (you guessed it) 68 feet of coax. The 2.1 swr went to over 3.1, mystery solved.....
.....anything less than 68 feet would result in a too high swr on 75 meters for most pi networks to handle it. This finding was duly reported to Charlie, with a recommendation that at least 100 feet of coax should be used for use on 75 meters for best results. When it went into production his ad in QST and the instructions packaged with the antenna said "should be used with at least 68 feet of coax".
Of course I have since learned why the longer coax showed a lower swr. I wonder if the legend would be different if I only had needed 34 feet to reach the shack. Of all my G5RV antennas that I have built, and I have built many, My conclusion is that it is a good tri-band antenna. 80,40 and 20 mtrs. Not an "all band" antenna. 300 ohm ladder line is a better choice than 450 ohm. The reason is that on 40 mtrs the 1/4 wave length better transforms the high center impedance nearer to 50 ohms than 450 ohm line. On 75/80 mtrs it is a 1/8 wave length feeding a very low impedance which results in adding inductive reactance to the system. And again 300 ohm line is better than 450 ohm which adds a bit too much inductive reactance. It would make no difference on 20 mtrs since it is a 1/2 wave length there and WYSIWYG on both ends of the line. Your mileage may vary. And like all wire antennas, the biggest factor for their performance are three things.....location...location and location.

You wouldn't notice much difference for a single band
and maybe not even for a tribander. The helical has a
greater bandwidth than the bunched. For instance, at:

http://www.k1ttt.net/technote/airbalun.html

there's an 8 turn helical Vs 8 turn bunched. If the
target choking impedance is 500 ohms minimum, the helical
covers 6-24 MHz, a 4:1 ratio, while the bunched covers
4-10 MHz, a 2.5:1 ratio. The helical also has about two
times the maximum choking impedance as the bunched one.

Here's an idea. Use the 11 meter antenna for 10 meter
operation by switching in a series capacitor. All you
need to do is to neutralize the small amount of inductive
reactance on 10m caused by the antenna being a tad too
long. The capacitor could be switched in and out by a relay.
I get a value of ~330 pf to perform that function. The
SWR on 10m will actually be better than it is on 11m.

Or you could use the capacitor with the second 102 inch
vertical without having to cut it.

Avoid any interaction at all by switching in a 330 pf
series capacitor for 10m operation and use one vertical
for both bands.

But before you do anything, measure the SWR of that
102 inch vertical on 10m. EZNEC says it will be only
about 1.5:1, close enough to a match for most people.

Or compromise and cut the vertical to resonance on a
frequency half way between 11m and 10m. I'll bet the
SWR will be acceptable on both bands.

It seems you were to lazy to find out that I already passed my code class.
For your information I use the CB to talk to truckers when I go into areas
Hit by hurricanes.
I was in gulf port mississippi 2 days after the hurricane hit that area
last year. The year befor I was in Florida 2 days after the hurricanes hit.
You see I dry out flooded buildings ...mostly hospitals...BTW I gave My 2
meter rig to the local EOC in gulf port last year. They needed it more than
I did.

So I use the CB to find out what roads are open, where the last place to
get fule is etc. We haul in most of our own fuel but we have to be able to
get fule for our big generators... And we also use the CB to talk to each
other on the road. we have had convoys of over 20 trucks ....

1311. Minimizing Common Mode Currents by Simple Grounding?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-10-24 00:41:37 UTC
From: Brian Kelly <kelly@dvol.com>
Message-ID: <1161650497.927010.19280@h48g2000cwc.googlegroups.com>
Source record: 50585

I'm in the process of stringing two base-fed half wave verticals up in a big beech tree, they're Dale Parfitt's End Fedz dipoles for 20 & 15M. These antennas are described on this Web page:

http://www.universal-radio.com/catalog/hamwire/4456.html

It seems to me that I have three options for feedline common mode current minimization/elimination. Beads, coiled coax chokes which is a quagmire I don't want to get into and plain old grounding. It's the "plain old grounding" option I'd like to run past the gurus around here for reality checks on my thinking.

The matching networks will be 12" - 18" inches above the the surface and fed with 8X coax. The tops of eight foot ground rods will be directly (+/-) below the matching network enclosures at the bases of the verticals. I'd split open the jacket of the coax and solder pigtails made from 3/8" flat braid to the coax shields just behind the PL-259 fittings then tape/goop the joints to weatherproof them. The other ends of the braid will be attached to the ground rods. There will also be some "nominal" radials attached to the ground rods.

Will this arrangement eliminate the need for the usual types of 1:1 choke baluns by taking any I3 currents on the coax shields straight to ground?

Thanks,

Brian w3rv

I ran a series of models of a typical G5RV in inverted V
configuration, modelling feedpoint Z using NEC2, and transmission line
and tuner losses. The models are reported at
http://www.vk1od.net/G5RV/index.htm .

I refer to Figure 3 which shows nominal 450 ohm ladder line and 15m of
RG58C/U feedline.

I have rerun the model with a feedline that is the same copper
dimensions as TV ribbon available here in Australia, but air
dielectric (in the absence of reliable measured loss characteristics
of the feedline). Real TV ribbon will be very slightly lossier.

Examining the loss on 80m, 40m, and 20m, the nominal 300 ohm line is
not a clear improvement over the nominal 450 ohm line in the model
scenario.

Here are the total loss figures (open wire line, coax, tuner) for the
model scenario:

450 300
3.6 2.4 3.3
7.1 1.9 1.4
14.2 1.0 1.7

Though the 300 line is a little better at 40m, it is a little worse on
80m and 20m.

The interaction of components of a G5RV antenna system are interesting... the case of 300 line at 3.6MHz is increased loss in the open wire section (no surprises there), and decreased loss in the coax section compared to 450 line.

A lower loss 300 ohm line (ie one with thicker conductors) would perform differently. One just doesn't know unless one runs the numbers.

Perhaps a "feeling" that something works better leads to urban myths?

The optimum length of coax in a G5RV feed is zero (metres or feet).

Owen

It seems that SC is too lazy to use qrz.com or read entire posts or he would know that I have my general and he would know that I use A CB for local information when I am in hurricane damaged areas.
Truck drivers always know what roads are open and where the last place to get fuel is. A CB is also nice when your in a convoy of trucks pulling generators and drying equipment.
SC you ever been in an area right after a major hurricane? I have spent months in them drying out hospitals and medical office buildings. Many time haveing to sleep in the halls of the buildings we are drying.
Say what you will but a CB has its uses and sometimes there is nothing else you could use in a hurry. When I get the phone call that we are going, I have between 3 and 6 hours to pack up and go. Besides what ever Tractor Trailers that are going with us already have CBs.
I could go into more detail about SC but I think he is starting to give Ham radio a bad name by his ignorant and insulting comments.
Joe

Ian White GM3SEK wrote:
> However, it's perfectly clear that Cecil's estimate of "40-50 turns"
> needed for a 75m choke is way off.

Wouldn't you say the number of turns depends upon the
diameter of the coil? How many turns would be needed
for 75m self-resonance if one were using RG-58 wound
on a 3 inch diameter PVC pipe?

Using the inductance formula in the ARRL Handbook,
40 turns on a 3 inch diameter form at 4 TPI is
about 32 uH or about 800 ohms on 4 MHz. The
distributed capacitance would lower it even farther.
40 turns on a 3" form would be an absolute minimum
for any high SWR situation on 75m.

> Right conclusion about the choke being useless a long way above its peak
> resonance - but not the right reason for it. The true reason is the very
> simple property of a parallel LC circuit (the inductance of the coil,
> resonated by its own self-capacitance) which means that far above
> resonance its parallel impedance drops to a very low value. That's what
> makes it useless at those frequencies.

Ian, your own graphs show transmission line effects. The fact
that the phase angle does NOT go to -90 degrees and stay there
proves those are transmission line effects. Here's what the
IEEE paper says:

"The concept of coil 'self-capacitance' is an attempt to
circumvent transmission line effects on small coils when the
current distribution begins to depart from its DC behavior."

"There are a great number of formulae for coil self-capacitance.
None are of particular value for quarter-wave helical resonators
anywhere near the 90 degree point."

Your parallel self-resonance *IS* the 90 degree point. I wish
you would take time out to realize that if there were no
transmission line effects, the phase angle would go to -90
degrees and stay there. Please set up a parallel inductor
and capacitor and see for yourself what happens as one
increases the frequency past parallel resonance. The phase
angle is asymptotic to -90 degrees.

> The 4.6MHz choke does have series resonances at about 23MHz 33MHz ,but
> those cannot be said to affect the performance of the choke in any

> practical way, because the choke doesn't have any usable performance at
> these frequencies anyway.

Those grapes were probably sour anyway. :-) Ian, a lumped
circuit inductor and parallel capacitance would NOT have
those series resonances. A lumped circuit would go to a
phase angle of -90 degrees and stay there while the impedance
drops inversely proportional to frequency. Seems to me, you have
just admitted that the chokes you wound are exhibiting transmission
line effects just as I predicted. (Except for the VF error I made.)

THE CHOKE DOESN'T HAVE ANY USABLE PERFORMANCE AT THOSE HIGHER
FREQUENCIES *BECAUSE* OF THE TRANSMISSION LINE EFFECTS!!!

> Cecil keeps resolutely ignoring the reservation: "within the practical
> working range of the choke".

That's circular logic, Ian. I said that series resonant
transmission line effects limit the practical working range of
a coax choke and you disagreed. Now you have proved I am
right with your own measurements on chokes of your own design.

If those actually were lumped inductors and capacitors as you
continue to assert, THE SERIES RESONANCES THAT YOU MEASURED
WOULD NOT AND COULD NOT EXIST!!!

The series resonant transmission line effects are the *CAUSE*
of the practical working range of the choke being limited.

In a parallel LC circuit, as the frequency increases, the
capacitive reactance becomes dominant and decreases inversely
proportional to frequency. The phase angle would be asymptotic
to -90 degrees. None of the measurements look anything like that.
All of the measurements exhibit transmission line effects.

> Within the frequency range where the choke has a practically useful
> value of impedance, there are no - repeat NO - signs of transmission
> line effects. Its behaviour is purely LC, its own inductance resonating
> with its self-capacitance.

This will be the forth time I have said this, Ian. If there were
no sign of transmission line effects, the phase angle would go to
-90 degrees and stay there. If the phase angle doesn't go to -90
degrees and stay there, that is *prima facie evidence* of transmission
line effects. Lumped parallel inductors and capacitors don't exhibit
the effects measured by you on the chokes that you wound.

>> Scale the high impedance points for 75m and the low impedance
>> bumps due to transmission line effects will occur in the
>> middle of HF.
>
> Hands-on measurements prove otherwise - the spurious resonances stay
> pretty much where they were, above 20MHz.

Uhhhhh Ian, 20 MHz *IS* HF! The transmission line 1/2WL series
resonant effects are occurring in the HF range! That's why the
75m choke doesn't work on 15m!!! 20-30 MHz is 37% of HF.

> As stated above, I measured a choke which is resonant at 4.6MHz. It has
> over 1000 ohms impedance at 3.5MHz, rising to over 2k at 4MHz, so it
> would be a very good performer on both 75m and 80m.

But it wouldn't make a good performer on 15m because of the
series resonant transmission line effects. That was my point
from the beginning. (The mistake I made was forgetting that the
VF of the choke changes with frequency.)

> It is ridiculous for Cecil to describe such a choke as "misbehaving and
> a very poor design".

This thread has not been about single-band or narrow-band chokes.
We were talking about broadband chokes being able to cover three
octaves of HF. The bunched coil choke is much more narrow-banded
than helical wound chokes thus rendering them virtually useless
for broadband operation. They *misbehave* in broadband (all-HF)
applications. They are a *very poor design* for broadband (all-HF)
applications.

Joe;

I can testify as to the usefulness of CB to obtain traffic conditions.
Last year I was coming up I57 when the truck drivers started talking
about a traffic jam just up the road. They mentioned dropping of the
highway and taking side roads. This information saved me over an hour
traffic delay. My wife had taken her own car and was stuck in the
traffic jam. CB radio has it's uses.

No argument there Owen, When I think back I remember at one time I used a commercial open wire TV line made by Saxton. It said it was a 300 ohm line. I suspect it was more like 400-500 line since it was #18 copperweld with a polystyrene spacer about every 2" with a wire spacing of about 7/8" That seemed to work the best on 75 as I remember. Go's along with what you have modeled I guess.

I've often thought I would like to lengthen the 300 or 450 line by a factor of 3 and still use a short length of coax just to get outside the shack. Is there such a thing as end effect with a feed line when computing multiple 1/2 wave lengths? Or do I just cut long, short the far end, and trim it using my MFJ-259. Also will the MFJ-259 be accurate when used in this manner with a line that is not 50 ohms? I think so, but not sure.

My only reason for using the G5RV at this QTH is that the 102' length just fits on my small lot. And I'm sure open wire feed all the way into a real balanced tuner (Johnson Matchbox etc) would be the best. But then it's not a "real" G5RV and no more urban myths.

John,

Perhaps you should be pleased that you can string out a 102' dipole...
that is good.

If you feed it with low loss parallel wire line (parallel wire wire
line is not synonymous with low loss) all the way to the balanced
tuner, you should be fine. If the configuration presents a load that
challenges the tuner, increase the line length a little.

Varney did make mention of the configuration using just parallel wire
transmission line, but most people don't understand that to be one of
the described variants. I would call it a G5rv, it is closer to a G5RV
than most implementations.

I'm afraid I don't understand your post at all. Perhaps you are kidding and I am fished in. So be it.

I do not understand how EMR can travel in any medium "faster" than in a vacuum. Regarding Ray's post, I don't have a precise definition of velocity factor but I suspect it is not describing wave propagation directly. (And I am speaking as a total mathematical pedestrian :)

Negative refraction is damned puzzling ... and fascinating. Richard seems to have the best links on the subject.

Disregard that idiot. If it were up to him, we'd give up all voice
communication and bang code out on each other's heads like cavemen. Of
course, that really sounds like a novel idea to try on S-L-O-O-O-W Code.

> . . .

Suppose you put a 1 GHz signal into a waveguide and stopped time so you could look at it. Measure the distance taken up by one complete cycle, and you'll find that it's greater than c/f. (In a vacuum, the distance is c/f, and in a medium with velocity factor less than 1 it's less.) Now start time up again, and look at just one spot along the waveguide. Sure enough, a whole cycle goes by every ns. Sure looks like it's going faster than c. This is the phase velocity.

But if you turn the signal off at one end of the waveguide and measure how long it takes for it to disappear at the other, dang. The change travels at the group velocity, which is never faster than the speed of light.

Hi Brian,

There are any number of curiosities about this link.
1. The antennas are marketed as half wave DIPOLES;
2. They have matching networks to 50 Ohms;
3. Some (if not all) have low power restrictions.

Why?

A half wave dipole already comes close enough to match as to beg the question: what more is necessary?

Well, the best interpretation is they are not DIPOLES at all. They are half wave monopoles which definitely demand matching. But with tinker toy sized components in that small box? Now we see why they are power restricted (those components would be toast).

>The matching networks will be 12" - 18" inches above the the surface

It sounds like it would be worth a try.

>Will this arrangement eliminate the need for the usual types of 1:1
>choke baluns by taking any I3 currents on the coax shields straight to
>ground?

Skip it. Go straight path to ground, and make sure the coax hugs the weeds all the way home. This will stabilize the match which is notoriously wild if you have too much cable trailing around in the open. Your concern for common mode is well founded.

Now, let's return to the technical howler of calling these antennas DIPOLES. This is marketing to the stupid, or by the stupid. Buy your own wire, and invest in quality components in a larger enclosure. This

will easily save half the cost and finding even a modest coil and cap in the junk box will save you a trip to the post office (and the cost of postage and handling). The worst you can do is equal the design. (OK, so some could do much worse.)

Still and all, the price is set at the disposable income level; buy two so you have a spare when the first one blows.

This discussion doesn't involve anybody's formula for self-capacitance. The coil resonates using whatever value of self-capacitance it has in

reality.

>Your parallel self-resonance *IS* the 90 degree point. I wish

>angle is asymptotic to -90 degrees.
>
I know what a parallel LC circuit does. The point you continue to evade is that, from VLF up to about 20MHz, this coil of cable behaves in exactly the same way.

The circuit looks inductive below the resonant frequency and capacitive above it, and passing through resonance the phase angle of the impedance flips from +90deg to -90deg... and then it stays very close to 90deg, clear up to about 20MHz. (The VNA reports angles of -88 to -89deg.)

>> The 4.6MHz choke does have series resonances at about 23MHz 33MHz

>
>If those actually were lumped inductors and capacitors as you
>continue to assert, THE SERIES RESONANCES THAT YOU MEASURED
>WOULD NOT AND COULD NOT EXIST!!!
>

That is the usual mixture of selective quoting and false logic. What you continue to overlook is that the behaviour all the way from DC

through the 4.7MHz resonance and onward up to about 20MHz can be accurately represented by nothing more elaborate than a simple LCR circuit. The fall in impedance from the resonant frequency up to about 20MHz is completely accounted for by just those three simple parameters: two reactances and one fixed loss resistance in parallel.

Above that frequency there are effects that the simple LCR model cannot account for. I have always said so, and yes, a transmission-line model could account for those.

>The series resonant transmission line effects are the *CAUSE*
>of the practical working range of the choke being limited.
>
That is simply not true. The limitation in working range is simply the shunting effect of the self-capacitance, which becomes increasingly important above resonance and causes a long progressive fall in impedance. This effect is very simple and entirely predictable. By 20MHz it has reduced the impedance to a hundred ohms or less, which means that the coil of cable is no use as a feedline choke for that frequency.

The series resonances above 20MHz cause further dips in impedance to only a few ohms, but those dips are quite localized in frequency. They are not the cause of the long progressive fall in impedance above the parallel resonance, which is what limits the usable bandwidth of the choke.

The challenge is still on the table, Cecil, for YOU to develop a quantified transmission-line model that will predict all the measured properties of a resonant choke over that wider range of frequencies.

The rest is snipped, because it's just you continuing your own argument with the straw-man you have manufactured. A self-resonant choke is not a wideband solution capable of cover the whole of HF. I never expected it to be, and never claimed it would be, so stop acting as if I had.

John, it's all relative...

You need to do some basic reading...
First for antenna knowledge:
Walter Maxwell's book, Reflections II - most highly recommended by me -
and will clear up why you can't just 'fold' half of the dipole EM
around the arc of a circle to get more gain...

The ARRL antenna Handbook - pay particular attention to the Smith Chart
instructional..
John Krause, W8JK's, college text on antennas called, 'Antennas'

For basic physics of EM waves
'Dummy' series on physics
Start with Richard Feynman's public lecture series of popular books,
especially his QED...
Any college level text on physics and optics..

For that special moment with a loved one:
Any popular level book on the Special Theory of Relativity...

Unfortunately for non speakers, like the language of Spanish is
spanish, the language of all science is mathematics... Get the 'Dummy"
series book on algebra and do enough of the problems so that basic
equations don't panic you... This alone will make most of the
university level science books accessible...

I'll leave the Calculus to your discretion

I use the 'Dummy' series of books for skimming any topic that I lack
the basics in... Well done for the most part - or maybe I just don't
'get' the ones I thought weren't well done, eh?..

cheers ... denny / k8do

Source record: 50601

Jeez RIchard, did we quaff a few too many pints of viper venom last
night? The guy asked for advice and got fanged...

Ignore Richard, Brian, his acerbic disembowling was aimed at the
purveyors of the antennas, not you...
However, having said that Richard is right as usual.. Forget those
guys...
Get some wire - Romex or THHN from Home Depot will work nicely... Or
any other source of #18 to #14 wire you can come up with...

Cut it to a half wave via formula:
983/F(mc) for 1 wave, then divide by 2 - exact length doesn't matter
because the tank circuit
will tune the antenna, just about no matter what..

Grab the nearest source of thin plastic bottle you can find that is
roughly 2" - 3" diameter...
- that bottle of designer water your sweetie carries around will work
just fine, just don't fess up when she asks if you have seen it...
And if you leave the water inside, you can tell the guys on the local
repeater, "Can you hear me now?" <oops, wrong commercial>
you can tell them that you are running so much power you had to water
cool the coils! -

Wind about 6 or 7 turns of bare wire on the bottle, spaced about a
wire diameter apart...
Get a variable cap, about 60 to 100 uuF will do nicely... Wire this
across the coil as a parallel tuned circuit...
Hook the braid of your coax to the bottom of the tank... The coax
center will have an alligator clip on it... The feed end of the antenna
goes to the top of the tank circuit <obviously>...
Tap the coil 1.5 to 2 turns up from the bottom with the alligator clip,
run low power, swing the cap and look for a dip (that is a 'dip' on the
SWR meter, not your fishing buddies)
Didn't dip did it? Probably because your tank didn't tune exactly to
the band you are on... Add or subtract turns to the tank coil until you
do see meter movement that says you are getting close... Then adjust
your tap point for that magic 1:1...

"One to one, one too one, we don't have no fun until it's one to
one"...

****
A short break for Bruno to to give me my medicine and adjust my
restraints...
Now I feel better!

****
**

Now the counterpoise... A ground rod will work after a fashion - so
will strychnine, but that is another story...
Better is radials, as many as you can put down - length does not
matter! Drop a wire from the bottom of your tank to the radials
center..
Better yet <best!> is an elevated counterpoise, half wave long, 2 feet
or higher above ground, the bottom of the tank/coax is tapped to the
center of the counterpoise... Ground rod is unnecessary, unless you
want to put an RF choke from the bottom of the tank to ground just to
bleed static electricity... Your call... The ground rod does nothing
otherwise, and may actually harm your antenna pattern if connected
directly to the tank...
(I know, I know, that's not what they taught you in Sunday School...
It's a cold, cruel world out there.)

Now the common mode choke... Well, you can order a premade choke from
WX0B (great folks, solid products, but definitely not cheap)
Or you can order a 0.5" X 4" iron powder rod from the usual suspects,
then get Formvar magnet wire and wind 6 bifilar turns on it... Then
solder this whole gaschmazz between the tank and the coax... It will
work nicely...
Or, you can stop reading all the Hennie Pennies who run around clucking
that the sky is falling down, wind 6 turns of your coax on a plastic
pail in about 90 seconds, and go for a beer because you are done - and
you have the best choke that money can buy...

BTW, you only have to put up one antenna for 20 because with a bit of
experimenting and a jumper or two, you can find the magic coil taps for
15 meters, also...

OK, Bruno says I will take a nap NOW, before I cause any more problems
on here....

I posted my measurements but I am handicapped by not being able to measure any impedance above 650 ohms. But I can sure see those series resonant points with my MFJ-259B. You know, the points that your lumped circuit model says do not exist?

> I know what a parallel LC circuit does. The point you continue to evade
> is that, from VLF up to about 20MHz, this coil of cable behaves in
> exactly the same way.

And falls apart above 20 MHz because of transmission line effects. Your lumped circuit model is a subset of the distributed network model. Of course, they will give similar results up to the point where the lumped circuit model falls apart.

> The circuit looks inductive below the resonant frequency and capacitive
> above it, and passing through resonance the phase angle of the
> impedance flips from +90deg to -90deg... and then it stays very close to
> 90deg, clear up to about 20MHz.

Yes, both models give similar results up to 20 MHz which is about half way around the Smith Chart. Then your model falls apart. The fact that the phase angle departs radically from -90 degrees in reality when your model predicts that it should stay at -90 degrees is prima facie evidence that your model has fallen apart. Your own phase graphs contradict what you are saying.

> That is the usual mixture of selective quoting and false logic. What
> you continue to overlook is that the behaviour all the way from DC
> through the 4.7MHz resonance and onward up to about 20MHz can be
> accurately represented by nothing more elaborate than a simple LCR
> circuit. The fall in impedance from the resonant frequency up to about
> 20MHz is completely accounted for by just those three simple parameters:
> two reactances and one fixed loss resistance in parallel.

Just proving that the lumped circuit model is a subset of the distributed network model and the two results are expected to be similar. But your model falls apart above 20 MHz where the transmission line effects are obvious.

> Above that frequency there are effects that the simple LCR model cannot
> account for. I have always said so, and yes, a transmission-line model
> could account for those.

I certainly don't remember you ever saying that but we are making progress. You are agreeing with me and we seem to have little argument left. What I seem to remember you saying is that it is "ridiculous" to model a parallel self-resonant choke as a transmission line. But my memory is not as good as it once was.

> That is simply not true. The limitation in working range is simply the
> shunting effect of the self-capacitance, which becomes increasingly
> important above resonance and causes a long progressive fall in
> impedance. This effect is very simple and entirely predictable. By 20MHz
> it has reduced the impedance to a hundred ohms or less, which means that
> the coil of cable is no use as a feedline choke for that frequency.

Your rose colored glasses are giving you false images. In the earlier example, the 12 turn choke had a maximum choking impedance at 15 MHz. At 23 MHz, the phase angle goes to -88 degrees just as both models predict. At 32 MHz, the phase angle is back to +20.4 degrees. Using your lumped circuit model, how does the phase angel get back to +20.4 degrees with that lumped capacitance dominating???

Ian, IF YOU ANSWER ONLY ONE QUESTION, PLEASE ANSWER THIS ONE. Exactly how does the phase angle get to +20.4 degrees at the exact time that your lumped circuit model is predicting -90 degrees??? (That's a 541% error!)

> The series resonances above 20MHz cause further dips in impedance to
> only a few ohms, but those dips are quite localized in frequency. They
> are not the cause of the long progressive fall in impedance above the
> parallel resonance, which is what limits the usable bandwidth of the
> choke.

You are attempting to use petitio principii to prove the validity of your model and I think you know that is a no-no. A similar long progressive fall happens with the distributed network model but it accurately predicts the transmission line effects proved by the bumps in the phase graphs that you provided.

Back to the previously discussed 12 turn choke. The impedance at 23 MHz is 955 ohms at -88 degrees, almost purely capacitive. Your "long progression" model would predict 686 ohms at -89 degrees for 32 MHz. Yet at 32 MHz, the impedance is measured to be 258 ohms at +20.4 degrees. Your lumped circuit "long progressive fall" model could not be any more wrong. Your impedance is off by 166% and your phase is off by 541%.

Please note that if your lumped circuit model were correct, the choke would still be performing pretty well at 32 MHz with a choking impedance of 686 ohms. Your above statement is thus proved false by the measured data.

> The challenge is still on the table, Cecil, for YOU to develop a
> quantified transmission-line model that will predict all the measured
> properties of a resonant choke over that wider range of frequencies.

My model, although not perfect, yields more accurate results than your model over that wider range of frequencies. My model predicts the bumps in the phase graphs. Your model predicts zero bumps in the phase graphs. Yet the bumps are obvious on your phase graphs. My model, a superset of yours, sure doesn't produce errors like 541%.

If you bothered to read my post there were NO attributions at all , just
quotes from the previous message in the thread that required no attribution.
So none of them were "Bad".

No my name is not David, as it clearly said at the end of the message. I was
not replying on David's behalf, merely commenting on the fact that respect
is not something that comes merely with an ability or a qualification; it
has to be earned by words and deeds. SC has not demonstrated anything here
that would earn respect; quite the opposite in fact.

> You can't even quote a Usenet post properly. Work on that before

Critiquing SC is not difficult, his rantings make that task very easy, Even
if his arguments did have any merit, his off-topic spam like postings debase
the whole point of view. It just looks like very childish behaviour.

From the IEEE Dictionary:
"dipole antenna - any one of a class of antennas having
a radiation pattern approximating that of an elementary
electric dipole."

Is the reflector on a single-band Yagi a dipole?

It's the international paperback edition in black and
white on non-glossy paper but contains all the information
in the domestic version. (The "fishy" part is that it's
a gray market book and not supposed to be available to US
citizens.)

I've used the duoband EF-20/40 (since replaced by the triband EF-10/20/40) for several years for portable QRP operation. The real advantage of these antennas for field operation is their light weight plus simple erection by tossing them into a tree :

http://users.vnet.net/btippett/cataloochee_divide_trail_qrp.htm

Dale W4OP is very knowledgeable and responsive. I would try a direct e-mail to him via par at parelectronics.com , however his FAQ page on the End-Fedz FAQ page states:

http://www.parelectronics.com/pdf/FAQ%20End%20Fedz.pdf

##
Q: Do the EndFedz require a ground?

A: The simple answer is no. With over 4000 antennas in the field, we know of one instance where RF was "in the shack." This occurred with the antenna directly over the operating position. Moving the antenna solved the problem. If you do ground the antenna at the matchbox, you will likely see no change in VSWR or resonant frequency. The only conditions where we were able to measure significant RF on the outer coaxial shield occurred when:

1. The coaxial length was an odd multiple of ¼ wavelength AND
2. The rig was grounded.
In this instance we measured current -7dB down from the peak antenna current.
Changing the coaxial feedline length OR removing the ground significantly reduced the currents.
##

Based on the above and my own experience (QRP rig plugged directly into the coax connector), I doubt you will need a ground. As I said before, ask Dale. He is extremely responsive and he seems to know what he is doing (see below).

http://www.parelectronics.com/index.html

73, Bill W4ZV

P.S. Since you want monobanders, you might consider rolling your own. I made one for 40m but wanted the versatility of Par's duobander for portable opertion. The designs below do require a counterpoise wire

but are quite easy to build. See multiple links at the bottom of this page for more info:

http://www.aa5tb.com/efha.html

> Why?

Why am I going to use them? Because they only cost fifty bucks apiece
delivered, I only have a barefoot 100W HF xcvr and I don't have to buy
or build two tuners before it gets too cold to mess with antennas.

> A half wave dipole already comes close enough to match as to beg the
> question: what more is necessary?

If I could install classic center-fed dipoles I would. But because of
the space-restricted installation geometry I'm dealing with I can't
pull the coax off at anywhere near a 90º angle to the vertical wire,
the coax would have to droop close to and parallel to the radiators
which would cause all sorts of problems.

> Well, the best interpretation is they are not DIPOLES at all.

Well . . this is a semantics & definitions issue as an ME I'll leave
for you EEs to sort out. I'm just another hobbyist who calls any
conductive structure with it's first resonance at a half wavelemgth of
some specific frequency a "dipole" independent of where it's fed and
how it's oriented. Which of course lays me open to the prospect of
getting gored good by purists and others who have copies of the IEEE
dictionary. But that's OK, I have scars all over m'bod and have
survived nicely.

> They are half wave monopoles which definitely demand matching.

Yes, they're two of Dale's "dipoles"installed as half wave monopoles.

> But with
> tinker toy sized components in that small box? Now we see why they
> are power restricted (those components would be toast).

I don't have an amp and they're well known for being considerably
underrated as far as power handing is concerned.

> (OK, so some could do much worse.)

I've built some number of tuners which could handle 2kW and then some
including one which used a 4" edge-wound roller inductor and a variable

cap with 1/4" plate spacing both remotely operated by giant Navy
surplus five-phase selsyns. Etc., etc., etc . . ad nauseam.

But right now all I want out of life is to get on 20 & 15 to snipe some
of the expeditions coming up this winter without having to fiddle with
the soldering iron. At some point after it warms up I'll do just what
you're suggesting, build robust tuners, use #10 wire for the radiator
and store the 100W "dipoles" for portable operations.

> Still and all, the price is set at the disposable income level; buy
> two so you have a spare when the first one blows.

I just might do that.

Thanks Richard.

Actually Brian, the IEEE Dictionary seems to agree with you.
It doesn't say a thing about the feedpoint position of dipoles.
Is an OCF a dipole? Is it a dipole if one of the poles is only
one inch long? The IEEE Dictionary seems to say that anything
that walks like a dipole, talks like a dipole, and radiates
like a dipole *is* a dipole, by definition. :-)

It's used to work out execution time

There is a call to a subroutine SECNDS . SECNDS is a built in function
in gnu FORTRAN that interrogates the computer clock

http://gcc.gnu.org/onlinedocs/gcc-4.0.3/gfortran/SECNDS.html

remove the "CALL" and it should work

>
>Why am I going to use them?

No. The "why?" was a rhetorical question about the three conditions
that were in conflict.

A halfwave dipole will match without need for extraneous components,
barring a choke which is for the consideration that brought you here.

>Because they only cost fifty bucks apiece

Priced to sell. How anyone can have grief with this is a mystery, but
you cannot imagine the mail that came my way. I enjoyed the mail, by
the way; however, only Dear Abby posts mail for response and education
to the interested.

>If I could install classic center-fed dipoles I would. But because of
>the space-restricted installation geometry I'm dealing with I can't
>pull the coax off at anywhere near a 90ï¿½ angle to the vertical wire,
>the coax would have to droop close to and parallel to the radiators
>which would cause all sorts of problems.

That is perfectly reasonable. If you have room for a halfwave end fed
wire, then you have room for the same sized sleeve dipole. Guess
what? It doesn't need matching as that comes free with the antenna.
It answers your problem about the 90ï¿½ angle: the feed comes out the
sleeve to exactly the same point the TWO you are buying do.

>> Well, the best interpretation is they are not DIPOLES at all.
>
>Well . . this is a semantics & definitions issue as an ME I'll leave
>for you EEs to sort out.

Hams (amateurs) use the same distinction; I'm afraid you are only
going to see the argument among "professionals" notably those late to
the linear world.

>> They are half wave monopoles which definitely demand matching.
>Yes, they're two of Dale's "dipoles"installed as half wave monopoles.

Hmm, rhetorically, you've just slipped into the abyss. Four
quarterwave elements? And how are you going to feed them? Two
halfwave elements? Didn't you say you had space limitations? Of
course you did.

If you were on the air and described your grounded dipole with a
matching box, I guess you would have a lot of rag-chewing in line.

>
>> But with
>> tinker toy sized components in that small box? Now we see why they
>> are power restricted (those components would be toast).
>
>I don't have an amp and they're well known for being considerably
>underrated as far as power handing is concerned.

I would have thought that might be part of the ad copy. I do note
that several are rated for less than 100W. I find that curious too
for a matching box that lends only .12dB loss.

That is about 1W of heat, not that I'm complaining, after all, a
Christmas tree bulb burns more heat than that and I would hardly call
that loss a limiting factor that demands derating from barefoot. A
copper coil can certainly tolerate that much heat - or just use bigger
wire.

OH! The capacitor will flash over? What are we talking about the
difference in a buck for a better cap? 5$? 10$?

Do we save $30 from NOT ordering the $50 backup, to simply change out
the under-rated cap for $20? Myself, I would pot the existing cap and
see what happens first (10 cents worth of epoxy).

That would change the tuning? OMIGOD!

>I've been concerned about missing
>something fundamental. Apparently I have not. Onward.

and upward.

You could download my slightly modiefied Nec2 source code at
http://home.ict.nl/~arivoors/Nec2dXS_src.zip

I once encountered similar problems. You could compare both sources to
see what I changed to overcome the error message.

Arie.

1349. Re: RoomCap Antenna

Hi,
many of you have been waiting long time for user
evaluations of the RoomCap antenna.
Here follows two recent reports:

(posted by Felix Meyer HB9ABX)

They speak for themself.

Betreff: Bravo -Room Cap Antenna
Datum: Fri, 20 Oct 2006 18:59:12 -0700 (PDT)
Von: Paul Ragany VE3UNF <........>
An: hb9abx.......

Hi Felix :

I have built the 20 meter version and it has reached more
than my expectations.
The antenna is fantastic - It is unbelieveable- I have been
comparing it to my G5RV and it out performs the G5RV .

Details:
Most tests were conducted between Tampa (Florida), my
location, and Toronto (Canada), VE3ZUH, over a distance
of 1700 km (1060 miles), using an FT-747 with 75 W output.

After two weeks, the results of my testing with VE3ZUH far
exceeded my expectations . VE3ZUH consistantly reports
2 s units better on the Roomcap compared to my G5RV.
I check in to the Maritime Net everyday on 14300.0 and
I consistantly get a strong 5 and 9 report from the net controllers
who are scattered all over the U.S. at various times of the day.
With the G5RV I get 5 and 8 to 5 and 9 reports.

On DX on Oct 19th I talked to OH2BH and OT4A (Belgium) -
they report 5 and 9 for my signal and I receive them at 5 and 7 .
On Oct 20th talked to Rob -HA503 FIN -special event station
in Hungary -he reports a 5 and 9 and I receive him at 5 and 7.
The G5RV was hearing 4 and 3to 5.

On receive, I average about 2 s units better about 50% of the time.
The signals are the same about 25% of the time and the G5RV
is about 2 s units better the other 25% of the time. I attribute that
to the 180 directionality if the G5RV (north/south).

Thanks for everything and we'll keep in touch, 73

Paul A Ragany VE3UNF

PS: The G5RV is 2 x 15,8 m about 9m above ground.
The RoomCap has a radiator of 1,5 m length,
installed on a wooden stand 1,2 m above ground.

An: hb9abx@.......

Hello Felix,

On my way back from work (Italy) to home (Belgium)
I had some time to visit you in Basel.

I was searching for a good antenna that is small in size.
Thanks to the Internet, I came across your website where
you published some information about your newly designed
RoomCap antenna.

I expected to see a mobile antenna that performed well,
I have seen other portable and mobile antennae, so I have
an idea as to what I might expect.
What I have seen was an antenna that, due to it�s design,
looked a little bit bulky.
This (maybe) disadvantage ��look�� was quickly forgotten
when we made the first QSO�s.

As simple as it can be, from the car with the TS50,
several qso�s were made.

No comparison with what I have experienced before
during other mobile HF operations.
Signal reports obtained were outstanding, even when
using a transmit power power of 10 Watts !

My impression of this antenna is very positive.
I�ve never seen any antenna performing like the one
you have on your car ! (taken into account the size of it)

I�m very glad that I�m now able to build my own.
Thank you for the good work !

Best Regards

Jan, ON6EJ

My latest judo move on the antenna I bought is that I returned the product to the seller, Universal Radio, called them a month later about an adjustment, had good success getting them to explain its assembly despite the directions, and agreed to have them send it to me again at their expense.

It was a tempest in a teapot anyways, because I only need the antenna for my apartment, which doesn't require assembly to a mast. I have it hanging in front of a window, and it looks like a little 2' Christmas tree. I wonder what will happen to signals if I put tinsel on it.

So the end of the story is that it functions okay, I'm okay with Universal Radio for doing me right, and thh'at's all ff'olks.

Source record: 50625

Chip antennas ? that I know, are conceptual monopoles. With an balun could
build an open dipole.
Using of diversity is a useful way to compensate polarity and directional
divergences in an array of them.
So the question is, why it must be a dipole?

Regards,

Ralf

Classic all the way and very much in the direction I plan to go. A few points though. I have an MFJ-259B analyzer which makes antenna tuning a piece of cake. By the time I get around to building any tuners I'll also have a grid dip meter which will take care of getting the tank circuit in-band on the bench instead of having to do it out in the weeds. And I'll probably see if I can wind coils like B&W does just because I've always admired them and it would be a challenge.
